(54) Title: COMPOSITIONS AND METHODS FOR ENHANCING HYBRIDIZATION SPECIFICITY

(57) Abstract

Compositions and methods are provided for increasing the specificity of a probe nucleic acid for a target nucleic acid in a hybridization solution. An abasic residue, deoxyNebularine residue, or a hybotropic is used to increase specificity. A method is provided for identifying useful hybotropes, including salts, water miscible organic solvents, aprotic solvents and organic solvents, on the basis of enthalpy considerations. Hybotropic hybridization and modified oligonucleotides may be used in amplification reactions, such as PCR, sequence analysis methods, and genomic screening methods.

COMPOSITIONS AND METHODS FOR ENHANCING HYBRIDIZATION SPECIFICITY

TECHNICAL FIELD

The present invention relates generally to compositions and methods for hybridization of oligonucleotides, and more specifically to certain solutions and/or oligonucleotide analogues which may increase hybridization specificity.

BACKGROUND OF THE INVENTION

The detection of diseases is increasingly important in prevention and treatments. While multifactorial diseases are difficult to devise genetic tests for, more than 200 known human disorders are caused by a defect in a single gene, often a change of a single amino acid residue (Olsen, *Biotechnology: An industry comes of age*. National Academic Press, 1986). Many of these mutations result in an altered amino acid that causes a disease state.

Sensitive mutation detection techniques offer extraordinary possibilities for mutation screening. For example, analyses may be performed even before the implantation of a fertilized egg (Holding and Monk, *Lancet* 3:532, 1989). Increasingly efficient genetic tests may also enable screening for oncogenic mutations in cells exfoliated from the respiratory tract or the bladder in connection with health checkups (Sidransky et al., *Science* 252:706, 1991). Also, when an unknown gene causes a genetic disease, methods to monitor DNA sequence variants are useful to study the inheritance of disease through genetic linkage analysis. However, detecting and diagnosing mutations in individual genes poses technological and economic challenges. Several different approaches have been pursued, but none are both efficient and inexpensive enough for truly widespread application.

Mutations involving a single nucleotide can be identified in a sample by physical, chemical, or enzymatic means. Generally, methods for mutation detection may be divided into scanning techniques, which are suitable to identify previously unknown mutations, and techniques designed to detect, distinguish, or quantitate known sequence variants.

Several scanning techniques for detection of mutations have been developed on the observation that heteroduplexes of mismatched complementary DNA strands exhibit an abnormal behavior, especially when denatured. This phenomenon is exploited in denaturing and temperature gradient gel electrophoresis (DGGE and TGGE, respectively) methods. Duplexes mismatched in even a single nucleotide

position can partially denature, resulting in retarded migration, when electrophoresed in an increasingly denaturing gradient gel (Myers et al., *Nature* 313:495, 1985; Abrams et al., *Genomics* 7:463, 1990; Henco et al., *Nucl. Acids Res.* 18:6733, 1990). Although mutations may be detected, no information is obtained regarding the precise location of 5 a mutation. Mutant forms must be further isolated and subjected to DNA sequence analysis.

Alternatively, a heteroduplex of an RNA probe and a target strand may be cleaved by RNase A at a position where the two strands are not properly paired. The site of cleavage can then be determined by electrophoresis of the denatured probe. 10 However, some mutations may escape detection because not all mismatches are efficiently cleaved by RNase A.

Mismatched bases in a duplex are also susceptible to chemical modification. Such modification can render the strands susceptible to cleavage at the site of the mismatch or cause a polymerase to stop in a subsequent extension reaction. 15 The chemical cleavage technique allows identification of a mutation in target sequences of up to 2 kb and it provides information on the approximate location of mismatched nucleotide(s) (Cotton et al., *PNAS USA* 85:4397, 1988; Ganguly et al., *Nucl. Acids Res.* 18:3933, 1991). However, this technique is labor intensive and may not identify the precise location of the mutation.

20 An alternative strategy for detecting a mutation in a DNA strand is by substituting (during synthesis) one of the normal nucleotides with a modified nucleotide, thus altering the molecular weight or other physical parameter of the product. A strand with an increased or decreased number of this modified nucleotide relative to the wild-type sequence exhibits altered electrophoretic mobility (Naylor et al., *Lancet* 337:635, 1991). This technique detects the presence of a mutation, but does 25 not provide the location.

Two other strategies visualize mutations in a DNA segment by altered 30 gel migration. In the single-strand conformation polymorphism technique (SSCP), mutations cause denatured strands to adopt different secondary structures, thereby influencing mobility during native gel electrophoresis. Heteroduplex DNA molecules, containing internal mismatches, can also be separated from correctly matched molecules by electrophoresis (Orita, *Genomics* 5:874, 1989; Keen, *Trends Genet.* 7:5, 1991). As 35 with the techniques discussed above, the presence of a mutation may be determined but not the location. As well, many of these techniques do not distinguish between a single and multiple mutations.

All of the above-mentioned techniques indicate the presence of a mutation in a limited segment of DNA and some of them allow approximate localization within the segment. However, sequence analysis is still required to unravel the effect of the mutation on the coding potential of the segment. Sequence analysis is a 5 powerful tool, allowing, for example, screening for the same mutation in individuals of an affected family, monitoring disease progression in the case of malignant disease, or for detecting residual malignant cells in bone marrow before autologous transplantation. Despite these advantages, the procedure is unlikely to be adopted as a routine diagnostic method because of the high expense involved.

10 A large number of other techniques have been developed to analyze known sequence variants. Automation and economy are very important considerations for implementation of these types of analyses. In this regard, none of the alternative techniques discussed below combine economy and automation with the required specificity.

15 A number of strategies for nucleotide sequence distinction all depend on enzymes, some very costly, to identify sequence differences (Saiki, *PNAS USA* 86:6230, 1989; Zhang, *Nucl. Acids Res.* 19:3929, 1991).

20 For example, restriction enzymes recognize sequences of about 4-8 nucleotides. Based on an average G+C content, approximately half of the nucleotide positions in a DNA segment can be monitored with a panel of 100 restriction enzymes. As an alternative, artificial restriction enzyme recognition sequences may be created 25 around a variable position by using partially mismatched PCR primers. With this technique, either the mutant or the wild-type sequence alone may be recognized and cleaved by a restriction enzyme after amplification (Chen et al., *Anal. Biochem.* 195:51, 1991; Levi et al., *Cancer Res.* 51:3497, 1991).

30 Another method exploits the property that an oligonucleotide primer that is mismatched to a target sequence at the 3' penultimate position exhibits a reduced capacity to serve as a primer in PCR. However, some 3' mismatches, notably G-T, are less inhibitory than others, thus limiting its usefulness. In attempts to improve this technique, additional mismatches are incorporated into the primer at the third position from the 3' end. This results in two mismatched positions in the three 3' nucleotides of the primer hybridizing with one allelic variant, and one mismatch in the third position from the 3' end when the primer hybridizes to the other allelic variant (Newton et al., *Nucl. Acids Res.* 17:2503, 1989). For this technique to be successful, it is necessary to 35 define amplification conditions that significantly favor amplification of a 1 bp mismatch.

DNA polymerases have also been used to distinguish allelic sequence variants by determining which nucleotide is added to an oligonucleotide primer immediately upstream of a variable position in the target strand. Based on this approach, a ligation assay has been developed. In this method, two oligonucleotide probes hybridizing in immediate juxtaposition on a target strand are joined by a DNA ligase. Ligation is inhibited if there is a mismatch where the two oligonucleotide probes abut.

Mutations may be identified via their destabilizing effects on the hybridization of short oligonucleotide probes to a target sequence (see Wetmur, *Crit. Rev. Biochem. Mol. Biol.* 26:227, 1991). Generally, this technique, allele-specific oligonucleotide hybridization, involves amplification of target sequences and subsequent hybridization with short oligonucleotide probes. An amplified product can be scanned for many possible sequence variants by determining its hybridization pattern to an array of immobilized oligonucleotide probes. Many of these techniques, especially allele-specific oligonucleotide hybridization, require establishing conditions that favor the hybridization of an exact match over a mismatch. As is well known, such conditions are difficult to achieve. One approach to improving hybridization is the addition of a chaotrope.

Chaotropes decrease the melting temperature of an oligonucleotide duplex (see Van Ness and Chen, *Nucleic Acids Research* 19:5143, 1991). Oligonucleotide probes (12-50 mers) possess some functional properties that are not shared by long DNA probes. These parameters include different rates of duplex formation as a function of (a) the difference between the hybridization temperature and the T_m , (b) stringency requirements for maximal selectivity/specificity of hybridization, and (c) sequence-specific anomalous behavior.

Chaotropes are useful in DNA probe-based diagnostic assays, as they can simultaneously lyse the cells of organisms of interest, inhibit nucleases and proteases, and provide adequate hybridization stringency without chemically altering the target analyte. Chaotropic lysis and hybridization solutions eliminate the need to isolate nucleic acid prior to conducting the DNA probe assay, and facilitate the development of rapid and simple assay formats (see Van Ness and Chen, *Nucleic Acids Research* 19:5143, 1991, for review). However, the commonly used chaotropes do not substantially increase the differential hybridization of matched/mismatched sequences.

In addition, special problems arise when hybridization methods are employed that involve the use of mixed pools of oligonucleotide probes (12- to 50-mers) having differing base sequences and G+C content. Many applications utilize

mixed pools of oligonucleotides and are frustrated by a host of problems. For example, many gene isolation strategies involve the reverse translation of a known polypeptide sequence into a set of all possible DNA sequences that can encode that protein (Jaye et al., *Nucl. Acids Res.* 11:2325-2335, 1983). A pool of oligonucleotide probes, 5 homologous to the set of possible protein encoding DNA sequences, are then used to screen a genomic or cDNA library from the relevant organism or cell type in order to identify the desired gene sequence. While the length of all of the oligonucleotide probes is the same, the G+C content of each probe may vary significantly, making the selection of hybridization conditions that are suitable and specific for each 10 oligonucleotide problematic. As a result, often many false positive clones will be selected when screening highly complex libraries for genes of low abundance.

This problem of simultaneously and accurately hybridizing many differing oligonucleotides of differing G+C content is even greater for sequence analysis of a specific region of DNA or identifying single base change mutations using 15 large arrays of oligonucleotides (which may vary from 100% A+T to 100% G+C) bound to a fixed surface (Southern et al., *Genomics* 13:1008-1017, 1992; Maskos and Southern, *Nucl. Acids Res.* 20:1675-1678, 1992). These methods, while theoretically powerful, have been sorely limited by the inability to identify hybridization conditions that will facilitate accurate hybridization (*i.e.*, no mismatch hybrid duplexes formed) 20 and allow all possible perfect hybrids to be stably formed.

One attempted solution has been to use a class of salts composed of small alkylammonium ions (most commonly tetramethylammonium (TMA⁺) and tetraethylammonium (TEA⁺)), that can greatly decrease the effect of base composition on DNA melting (Marky et al., *Biochemistry* 20:1427-1431, 1981; De Murcia et al., 25 *Biophys. Chem.* 8:377-383, 1978; Melchior and Von Hippel, *Proc. Nat. Acad. Sci. USA* 70:298-302, 1973). Of the tetraalkylammonium salts, only TMA⁺ and TEA⁺ are small enough to fit into the major groove of the B-form DNA double helix where they bind to the A+T base pairs of DNA (perhaps to the O-2 of thymine) (*see* De Murcia et al., *Biophysical Chemistry* 8:377 1978). The overall effect on stability is two-fold with the 30 first being that the tetraalkylammonium salts increase the non-polar character of the solvent which destabilizes the base stacking interactions in native DNA (*see* Rees et al., *Biochemistry* 32:137, 1993). The second effect is that the A+T base pairs are stabilized. Specifically, TMACl prevents DNA premelting by decreasing the transient openings between the base pairs from occurring below the melting temperature (*see* De Murcia et 35 al., *Biophysical Chemistry* 8:377 1978; Marky et al., *Biochemistry* 20:1427, 1981). The exact nature of TEACl stabilization is not known. Overall, the A+T pairing is stabilized

resulting in a rise in the melting temperature for the A+T pairs (see Marky et al., *Biochemistry* 20:1427 1981; De Murcia et al., *Biophysical Chemistry* 8:377 1978). For 100% A+T oligonucleotide duplexes, the T_m in TMACl is actually 6°C higher than that found in a sodium solution (see Marky et al., *Biochemistry* 20:1427, 1981).

When genomic DNA is melted in TMACl or TEACl at the specific concentrations of 3M and 2.4M, respectively, identical melting temperatures are exhibited for A+T and G+C pairs (see Melchior et al., *Proc. Natl. Acad. Sci. USA* 70:298, 1973). Usually what is observed is that synthetic DNA duplex stability in concentrated TMACl and TEACl stability is somewhat diminished and has little base compositional dependence (see Wood et al., *Proc. Natl. Acad. Sci. USA* 82:1585 1985; Marky et al., *Biochemistry* 20:1427 1981; Jacobs et al., *Nucleic Acids Res.* 16:4637, 1988). For example, a series of 19-mers ranging from 26% G+C to 79% G+C content had melting temperatures over a range of 18°C in 2X SSC, while in 3M TMACl the range narrowed to 5°C and in 2.4M TEACl, the temperatures were virtually unchanged negating all influence from G+C content (see Jacobs et al., *Nucleic Acids Res.* 16:4637, 1988). TEACl had the added benefit of reducing the melting temperature approximately 22°C over TMACl and SSC (see Jacobs et al., *Nucleic Acids Res.* 16:4637, 1988). When various lengths of hybridization probes are measured and the corresponding melting temperatures plotted versus length, the plot is a smooth curve even though the G+C content varied from 31-66% (see Wood et al., *Proc. Natl. Acad. Sci. USA* 82:1585 1985). In addition, the width of the melting curve, or the HCT, for natural DNA fragments is significantly reduced in TMACl (1°C) than in sodium solutions (5-10°C) (see Wood et al., *Proc. Natl. Acad. Sci. USA* 82:1585 1985). Narrowing of the HCT is indicative of the stabilization of the A+T pairing since the A+T pairs normally melt at a lower temperature than the G+C pairs creating broad melting curves.

In the context of gene isolation from complex libraries, the number of false positive clones isolated using a 17-mer mixed oligo pool (G+C range of 47% to 71%) was reduced 100-fold when performed in 3 M TMACl rather than using a NaCl hybridization solution (Wood et al., *Proc. Natl. Acad. Sci. USA* 82:1585-1588, 1985). However, even when using TMACl to eliminate the base composition effect on T_m , a significant number of false positive clones are still isolated due to formation of mismatched hybrids.

Using deoxyinosine at the third codon position (Honoré et al., *J. Biochem. Biophys. Methods* 27:39-48, 1993) of highly degenerate oligonucleotide pools from backtranslated protein sequences allows the oligonucleotide pool size to be

significantly reduced. However, when screening a more complex genomic library for clones, the isolation of false positive clones may still be a significant problem (Jacobs et al., *Nucl. Acids Res.* 16:4637-4650, 1988). While the presence of tetramethylammonium and tetraethylammonium salts made oligonucleotide melting 5 independent of base composition, there was no or little effect of mismatches on the thermal melting of oligonucleotides. That is, duplexes containing a mismatch had a similar T_m to duplexes which were perfectly base-paired.

Another method used to enhance specificity in hybridization reactions creates base mismatches using base analogs to replace any of the A, G, C, or T 10 nucleotides. Research has shown that some primers containing a base pair mismatch have increased specificity when the mismatch is placed in precise locations (see Wenham et al., *Clinical Chemistry* 37:241, 1991; Newton et al., *Nucleic Acids Research* 17:2503, 1989; Ishikawa et al., *Human Immunology* 42:315, 1995). However, differences of as little as 0.5°C in the melting temperatures are equally common 15 between perfectly matched hybrids and the same hybrid with a single base mismatch introduced (see Tibanyenda et al., *European Journal of Biochemistry* 139:19, 1984; Werntges et al., *Nucleic Acids Research* 14:3773, 1986). Even better specificity has been noted between one and two base mismatched duplexes than has been observed between a perfectly matched duplex and the same duplex with a single mismatch (see 20 Guo et al., *Nature Biotechnology* 15:331, 1997). Guo et al. found a (T_m of 4°C between zero and one mismatches and a ΔT_m of 13°C between one and two adjacent mismatches for a 20-mer duplex. However, even with two mismatches, often there is still little destabilization of the duplex. This inability to consistently discriminate mismatches 25 lends to the lack of specificity in PCR.

The use of more than one base pair mismatch per hybridization employing at least one nucleotide analog has been evaluated (see Guo et al., *Nature Biotechnology* 15:331, 1997). In this case, the analog compound consists of 3-nitropyrrole replacement of the purine or pyrimidine bases. 3-Nitropyrrole has the 30 ability to minimally hydrogen bond with all four bases (see Nichols et al., *Nature* 369:492, 1994; Bergstrom et al., *Journal of the American Chemical Society* 117:1201, 1995). By introducing an artificial mismatch, large differences in the duplex melting temperatures occur ranging from approximately 5°C to 15°C with the largest difference occurring when the mismatch is located at the center of the 15-mer hybridizing oligo. Significant differences in ΔT_m occur when an artificial nucleotide is introduced into a 35 duplex that already contains a base mismatch creating a two-mismatch duplex. The degree of destabilization depends upon the type of base mismatch (e.g., G/T) and the

separation between the two mismatches. In experimental examination, the base analog nucleotide ranged from 1 to 7 bases to the 3' side of the base mismatch, which was held in the center of the 15-mer. Differences in ΔT_m for the three different base mismatched 15-mers ranged from a 2°C stabilization (in the C/T mismatch case only and when the 5 mismatches are adjacent) to a 7°C further destabilization with the maximum destabilization consistently occurring at a 3 or 4 base mismatch separation (see Guo et al., *Nature Biotechnology* 15:331, 1997).

When two artificial mismatches are introduced, the proximity of the artificial bases greatly influences the degree of destabilization. The two artificial 10 mismatches were centered on the middle of a 21-mer duplex beginning with a separation of 6 bp. The destabilization, or ΔT_m , is minimally 12°C when compared to the perfectly matched duplex. The greatest difference of over 20°C occurs when the two artificial mismatches are 10 base pairs apart. This difference corresponds to one helical turn and indicates that some kind of interaction occurs between the two artificial 15 bases that decreases the stability of the duplex.

Experimentally, when the PCR primer utilized contained one or two artificial mismatches between the primer and the DNA sample, the PCR gave results as would be expected for a perfectly matched primer (see Guo et al., *Nature Biotechnology* 15:331, 1997). However, when the primer contained both a true and an artificial 20 mismatch, the PCR failed to produce any measurable results; while PCR with perfectly matched and true mismatches all produced measurable amounts of PCR product. The same study found similar results when using hybridization probes: those with perfect matches, true mismatches and artificial mismatches annealed while the probes containing artificial and true mismatches did not. These studies indicate greater 25 specificity is created when artificial base mismatches are incorporated in hybridization reactions such that when naturally occurring mismatches occur, they are thermodynamically less stable than a perfectly matched hybridization reaction and thus less likely to produce a false positive in an assay or PCR. Interestingly, however, the difference in thermodynamic stability noted above for duplexes containing only 30 artificial mismatches is not manifested in the experimental situation.

A further means of effecting hybridization discrimination is through differences in the stability between hybridization duplexes that contain nicks and gaps. In these reactions, duplexes are formed from tandemly stacked short oligomers hybridized to a longer strand that either align contiguously or non-contiguously leaving 35 a few base pair gap. Hybridizations that result in a nick are subject to "stacking hybridization" where another DNA strand hybridizes across the nick site. Stacking

hybridization does not occur where gaps are present in the non-contiguous oligomers. The stacking has the effect of increased discrimination as evidenced by decreased dissociation rates and greater thermodynamic stability than the non-contiguous counterparts (see Lane et al., *Nucleic Acids Res.* 25:611, 1997). Thermodynamic 5 measurements show differences between the hybridization stacked duplexes standard free energy change (ΔG) and the gapped duplexes is 1.4 to 2.4 kcal/mol. Therefore, discrimination in hybridization can be afforded through the use of multiple short probes.

Most of the base mimics in current use are the result of the pursuit for a universal base. Many utilize nitroazole base analogues and have demonstrated reduced 10 discrimination in base pairing. A series of nitroazole nucleobase analogues have been studied in attempts to gain additional insight into the significance of electronic structure and heterocyclic size in base pairing for the development of more effective universal bases (see Bergstrom et al., *Nucleic Acids Res.* 25:1935, 1997). In this work, the thermodynamic properties of the deoxyribonucleosides of 3-nitropyrrole, 4-nitropyrazole, 4-nitroimidazole, and 5-nitroindole were measured. For comparison, 15 thermodynamic measurements were also made on the deoxyribonucleosides of hypoxanthine and pyrazole as well an abasic spacer, 1,2-dideoxyribose. Four oligonucleotides were synthesized for each modified nucleoside in order to obtain duplexes in which each of the four natural bases was placed opposite the base mimic. 20 All of the base mimics analyzed proved to be far less stable than the natural base pairings (A+T: $T_m = 65.7^\circ\text{C}$, C+G: $T_m = 70.5^\circ\text{C}$) with the T_m 's ranging from 35-46°C for 5-nitroindole to 18-29°C for the other nitroazole bases analyzed. The only exception was 4-nitroimidazole paired with dGTP where the T_m was 40.9°C. In analyzing the free 25 energy for the duplex melting, the 3-nitropyrrole base mimic was found to have the least discrimination when pairing with any of the four naturally occurring bases with an overall ΔG of 0.4kcal/mol. The next least discriminating was 5-nitroindole with a ΔG of 0.8 kcal/mol. Both of these values are less than the ΔG of 1.1 kcal/mol found between the natural base pairings of A+T and G+C. 4-Nitropyrazole showed a slight 30 preference for pairing with A with a ΔG of 1 kcal/mol more stable than C, G, and T free energies. Finally, 4-nitroimidazole showed a high selectivity for pairing to G (as was evidenced by its high T_m value) due to the ability of the imidazole N3 to hydrogen bond with the deoxyguanosine N1. It should be noted, however, that the above values are 35 dependent upon the nearest base neighbors to the mimic. Further studies altered the nearest neighbors and found that 3-nitropyrrole and 5-nitroindole are quite non-discriminating base pairing partners.

Of interest, the enthalpy and entropy changes were found to track one another (*i.e.*, a large enthalpy change correlates to a large entropy change) regardless of the base mimic utilized implying that the correlation between ΔS and ΔH is independent of the mode of association of the bases. What was observed was that small enthalpy 5 and entropy changes were found in the non-hydrogen bonding base mimics. The low values for entropy change reflect the greater degree of freedom of movement possible for bases that are not locked into the duplex by hydrogen bonding interactions. The small enthalpy changes reflect alterations in hydrogen bonding interactions as a result of the loss of hydrogen bonding interactions for the base opposite the base mimic. If a 10 natural base remains stacked in the helix without an opposing hydrogen bonding partner then it has lost hydrogen bonding interactions with water without regaining a new donor/acceptor partner.

A similar study involved examining acyclic nucleoside analogues with carboxamido- or nitro-substituted heterocyclic bases (see Aerschot et al., *Nucleic Acids Res.* 23:4363, 1995). Utilization of acyclic nucleosides endows the constructs with enough flexibility to allow good base stacking as well as allow the base mimics to obtain an orientation to best base-pair with the corresponding base. The heterocyclic bases examined included: 4,5-imidazoledicarboxamide, 4-nitroimidazole, and 5-nitroindazole. These complexes were referenced against acyclic hypoxanthine, 1-(2-deoxy-(-D-ribofuranosyl)-3-nitropyrrole, 5-nitroindole, and 2-deoxyinosine. All the new acyclic complexes had melting temperatures 7-20°C less than those observed for the natural bases. 5-Nitroindazole when paired against each of the four natural bases had the least spread in ΔT_m of only 2.2°C while the 4-nitroimidazole had a spread of 8.0°C with dG being significantly out of line with the other three bases as had similarly 20 been observed above. Of the reference compounds, deoxyinosine had a ΔT_m of 5.6°C, 5-nitroindoles ΔT_m was 1.0°C, 1-(2(-deoxy-(-D-ribofuranosyl)-3-nitropyrrole had a ΔT_m of 5.1°C, and the ΔT_m of acyclic hypoxanthine was 4.8°C. However, all base mimics 25 showed about the same destabilization (ΔT_m of 4-5°C) when placed in an oligo consisting almost exclusively of adenosines with exception of 4-nitroimidazole and 30 acyclic deoxyinosine that had ΔT_m s of 7.0°C and 8.9°C, respectively.

Aerschot and co-workers also examined the effect of incorporation of multiple base mimics into an oligo (see Aerschot et al., *Nucleic Acids Res.* 23:4363, 1995). Overall, melting temperatures dropped but most markedly with the incorporation of three base mimics. The nitroindoles, however, showed the least 35 amount of temperature differential.

Another base mimic, 1-(2(-deoxy-(-D-ribofuranosyl) imidazole-4-carboxamide (Nucleoside 1), mimics preferentially dA as well as dC nucleosides (see Johnson et al., *Nucleic Acids Res.* 25:559, 1997). The ability to substitute for both dA and dC results from rotation about the carboxamide/imidazole bond as well as the bond between the imidazole and furanose ring. When the imidazole is anti to the furanose and the carboxamide group is anti to the imidazole, the lone pair on the oxygen and one of the amide NH hydrogens is in a position that mimics the NH₂ and N-1 of adenosine. Imidazole rotation about the glycosidic bond to the syn orientation places the amide group in a position that approximately matches the positions of the NH₂ and N-3 of cytosine.

When Nucleoside 1 is substituted for any naturally occurring nucleoside, the enthalpy increases with the greatest increase for a dG substitution for the 1-C pairing (from $\Delta H = 74.7$ (kcal/mol)/ $\Delta G = -16.5$ (kcal/mol) for the G/C pairing to $\Delta H = -45.5$ (kcal/mol)/ $\Delta G = -5.8$ (kcal/mol)). The smallest enthalpy change occurs for a dA substitution ($\Delta H = -72.9$ (kcal/mol)/ $\Delta G = -15.4$ (kcal/mol) for A/T pairing to $\Delta H = -66.7$ (kcal/mol)/ $\Delta G = -11.7$ (kcal/mol) for the 1-T pairing). Correspondingly, T_m significantly decreases from 65.7°C and 70.5°C for the A-T and C-G couples, respectively, to 46.6°C for the 1-T pairing, 43.4°C for 1-G, 27.6°C for 1-A, and 14.6°C for 1-C.

When used in a PCR reaction, Nucleoside 1 and its N-propyl derivative are preferentially incorporated as dATP analogues (see Sala et al., *Nucleic Acids Res.* 24:3302, 1996). However, once incorporated into a DNA template, their ambiguous hydrogen bonding potential gave rise to misincorporation of any of the naturally occurring bases at frequencies of 3×10^{-2} per base per amplification. Most of the substitutions (primarily consisting of G) were a result of rotation about the carboxamide bond when part of the template. Between 11-15% of the substitutions were due to rotation of the imidazole moiety about the glycosidic bond. As part of a DNA template, the N-propyl derivative behaved in the same way as Nucleoside 1 despite its propyl moiety. This study indicates that while Nucleoside 1 preferentially behaves as dATP, it has the ability in a PCR type environment to behave as all four naturally occurring nucleotides as well. From this and the above studies, it is evident that a wide range of duplex stability can be obtained through variations in base mimics and their placement within an oligonucleotide.

Petruska et al., *Proc. Natl. Acad. Sci. USA* 85:6252-6256, 1988, have reported on the correlation between the thermodynamic stability of mismatched primers and DNA polymerase fidelity. By analyzing the melting profiles of a perfectly based

paired primer with a A/T correct match at the 3'-end compared to primers that had either the incorrect base pair G/T, C/T, or T/T it was noted that there was a shift in free energy changes upon dissociation ($\Delta\Delta G^0$) of 0.2, 0.3 and 0.4 kcal/mole for the terminal A/T compared to the G/T, C/T, or T/T mismatches. Interestingly, the A/T mismatch was 5 extended (Drosophila DNA polymerase) about 200 times faster than the G/T mismatch and about 1400 and 2500 times faster than the C/T and T/T mismatched respectively. The authors hypothesized that the binding cleft of the polymers excludes water and amplifies by amplifying free energy differences by increasing enthalpy differences in mismatched primers.

10 Livshits et al., *J. Bimolecular Structure and Dynamics* 11:783-795. Adenine Press, ISSN 0739-1102, has presented interesting data and theoretical considerations of dissociation curve of oligonucleotides immobilized in gel-based arrays. The gel introduces a complicating factor of having to account for the effect of diffusion on the dissociation process. However, there was agreement between the 15 calculated and experimental dissociation temperatures due in part to enthalpy/entropy compensation.

Many DNA hybridization-based diagnostic tests are being developed to identify persons who might be suffering from (or be predisposed to) specific genetic diseases (see for example, Norari et al., *Gene* 43:23-28, 1986) or to determine a genetic 20 histocompatibility profile, which is useful for tissue matching between donor and patient (e.g., for a bone marrow transplant) (Sorg et al., *Eur. J. Immunogen* 19:391-401, 1992). However, significant problems are encountered when trying to develop simple and reliable hybridization methods using allele-specific oligonucleotide probes that differ in sequence at one nucleotide position. Norari et al. solved the mismatch 25 hybridization problem by the addition of 10-times more unlabeled complementary oligonucleotide than the mismatched labeled oligonucleotide. However, this is an impractical solution when multiplex hybridization methods are being used.

Diagnostic tests that rely on the polymerase chain reaction (PCR) technique also experience problems associated with the hybridization of 30 oligonucleotides. Rychlik (*BioTechniques* 18:84-90, 1995) examined the effects on PCR of varying the G+C content of primers at either the 5' or 3' end of a priming oligonucleotide. Using standard PCR buffers and conditions, oligonucleotides having a high G+C content at the 3' end (the end used to extend DNA synthesis during PCR) results in high priming efficiency, but also promotes false priming due to greater 35 tolerance for mismatches at the 5' end. Moreover, the effects of mismatches in PCR are variable; mismatches located in the middle of a primer-template duplex do not

significantly affect the efficiency of PCR amplification, while 3'-terminal base mismatches sometimes strongly affects PCR product yield. As a further complication, the strength of the effect that the various base pair mismatches have on PCR amplification is not the same as that observed for oligonucleotide hybrid formation and 5 stability (Ikuta et al., *Nucl. Acids. Res.* 15:797-811, 1987; Jacobs et al., *Nucl. Acids Res.* 16:4637-4650, 1988).

The present invention provides methods and compositions for detecting base changes by improving the specificity and accuracy of hybridization of an oligonucleotide with a target DNA sequence, and further provides other related 10 advantages.

SUMMARY OF THE INVENTION

This invention generally provides compositions and methods to increase the specificity of hybridization of nucleic acids.

In one aspect, the invention provides a composition comprising a nucleic 15 acid and a salt, the salt comprising an anion and a cation, the anion selected from halogenated acetate, propionate and halogenated propionate, the cation selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

In another aspect, the invention provides a composition which is non- 20 flowing comprising a oligonucleotide of 6-100 nucleotides and a salt, the salt comprising an anion and a cation, the anion selected from acetate, halogenated acetate, propionate, and halogenated propionate, the cation selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms. A "non-flowing" composition does not flow, as 25 solutions flow during chromatography.

In another aspect, the invention provides a composition which is free 30 from organic solvent, comprising a oligonucleotide of 6-100 nucleotides and a salt, the salt comprising an anion and a cation, the anion selected from acetate, halogenated acetate, propionate, and halogenated propionate, the cation selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

In another aspect, the invention provides a composition which includes a nucleic acid and a salt, where the nucleic acid is immobilized on a solid support, and the salt is formed from an anion and a cation, the anion selected from acetate, halogenated 35 acetate, propionate and halogenated propionate, the cation selected from primary,

secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

In another aspect, the invention provides a salt selected from the group:

- (a) an acetate salt of a cation of the formula $\text{HN}(\text{CH}_3)_2\text{R}_a$ wherein R_a is a $\text{C}_4\text{-C}_8$ hydrocarbyl;
- (b) a halogenated acetate salt of a cation of the formula $\text{HN}(\text{CH}_3)_2\text{R}_b$ wherein R_b is a $\text{C}_7\text{-C}_{12}$ hydrocarbyl;
- (c) acetate and halogenated acetate salts of a cation of the formula $\text{H}_2\text{N}(\text{C}_5\text{-C}_8\text{cycloalkyl})\text{R}_c$ where R_c is a $\text{C}_1\text{-C}_{12}$ hydrocarbyl; and
- (d) acetate and halogenated acetate salts of N-substituted piperidine, wherein the nitrogen atom of piperidine is substituted with $\text{C}_1\text{-C}_{12}$ hydrocarbyl. Such salts may be prepared by combining the respective acid and bases.

In another aspect, the invention provides an oligonucleotide in solution, where an oligonucleotides if formed, at least in part, from a plurality of fragments, each fragment shown schematically by structure (1)

wherein,

20 represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

 represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B_1 and B_5 ;

25 the specificity spacer having steric and chemical properties such that

(a) it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

In addition, the specificity spacer has at least one of the following properties: it cannot enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2); it can enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2), however it does not hydrogen-bond through any of adenine, guanine, cytosine, thymine or uracil according to standard Watson-Crick hydrogen bonding.

In another aspect, the invention provides an array, where the array includes a plurality of oligonucleotides immobilized in an array format to a solid support. Each oligonucleotide of the plurality is formed, at least in part, from a plurality of fragments, each fragment shown schematically by structure (1)

15 wherein,

represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

20 represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B₃ and B₅; the specificity spacer having steric and chemical properties such that

(a) it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

25

In addition, the specificity spacer has at least one of the following properties: it cannot enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2); it can enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary

base sequence of structure (2), however it does not hydrogen-bond through any of adenine, guanine, cytosine, thymine or uracil according to standard Watson-Crick hydrogen bonding.

In another aspect, the invention provides a composition which includes 5 an oligonucleotide and a salt in solution, the oligonucleotide being formed, at least in part of a plurality of fragments, each fragment shown schematically by structure (1)

wherein,

10 $\text{B}_1 \text{ B}_2 \text{ B}_3$ represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

— represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B_1 and B_5 ;

15 the specificity spacer having steric and chemical properties such that

(a) it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

20 , and

at least one of (b) and (c) where

(b) the specificity spacer cannot enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of 25 structure (2);

(c) the specificity spacer can enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary sequence of structure (2) but the specificity spacer does not provide any base selected from adenine, guanine, thymine, uracil or cytosine for the hydrogen bonding;

30 and the salt is a hybotrope.

In another aspect, the invention provides an array composition formed, at least in part of a plurality of oligonucleotides immobilized in an array format to a solid support, each oligonucleotide of the plurality formed, at least in part of a plurality of fragments, each fragment shown schematically by structure (1)

5

wherein,

10 B_1, B_2, B_3 represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

15 --- represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B_1 and B_5 ;
 the specificity spacer having steric and chemical properties such that
 (a) it does not prevent hybridization between a fragment of structure
 (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

20 at least one of (b) and (c) where

25 (b) the specificity spacer cannot enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2);
 (c) the specificity spacer can enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary sequence of structure (2) but the specificity spacer does not provide any base selected from adenine, guanine, thymine, uracil or cytosine for the hydrogen bonding; and the nucleic acid of formula (1) being in contact with a hybridope.

30 In yet other aspects, methods are provided for distinguishing between hybridization of a complementary nucleic acid target and a nucleic acid probe in which

the probe and target are either perfectly complementary or have one or more base mismatches, comprising the steps: (a) mixing the target and probe in a solution comprising a hybotrope; and (b) hybridizing at a discriminating temperature; and detecting the amount of probe hybridized to the target, thereby determining whether the 5 duplex is perfectly complementary or mismatched. In preferred embodiments, the probe or target is from 6 to 40 bases. In another preferred embodiment, the probe is labeled. In a related aspect, the probe has one or more abasic residues and the solution does not contain a hybotrope. In a preferred embodiment, the hybridization reaction mixture comprises a hybotrope.

10 In yet another aspect, methods are provided for increasing discrimination in a nucleic acid synthesis procedure, such as polymerase chain reaction. In these methods, a single stranded nucleic acid target is mixed with an oligonucleotide primer or a solution comprising a hybotrope and a polymerase, the primer is annealed to the target at a discriminating temperature, and a complementary strand to the target is 15 synthesized. The amount of duplex formed for a mismatched primer and target is less than for a perfectly matched primer and target.

20 These and other aspects of the present invention will become evident upon reference to the following detailed description and attached drawings. In addition, various references are identified below and are incorporated by reference in their entirety.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a graph illustrating thermal melt profiles of oligonucleotide duplexes. Percentage single strand DNA (α , y-axis) is plotted versus temperature (x-axis). The T_d of the duplex is defined as the temperature at which 50% of the strands 25 are in single strand form. The helical coil transition (HCT) is defined as the temperature difference between an α of 0.2 (or 20%) and 0.8 (or 80%). The melting curve denoted by the squares represents the behavior of a duplex in contact with a hybotrope (e.g., LiTCA) and the melting curve denoted by the diamonds represents the behavior of an oligonucleotide duplex in a NaCl-based hybridization solution.

30 Figure 2 is a graph illustrating the relationship of the T_d of an oligo duplex and salt concentration in hybridization solutions (LiTCA, GuSCN, NaSCN, NaClO₄, KI, NaCl, GuCl, CsTFA). The T_d in degrees C is plotted versus molarity of the salt.

35 Figure 3 is a graph showing the difference in T_d between two duplexes, one that is perfectly base-paired and the other that contains a single mismatch. The

temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis).

Figure 4 is a graph displaying melting profiles for an 18-mer oligonucleotide duplex that is perfectly base paired (diamonds) and the same 5 oligonucleotide duplex that contains a central mismatch (squares A/A, position 9). The ΔT_d is 6 $^{\circ}$ C. The melting profiles were determined in 2.0 M LiTCA. The percentage single strand (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis).

Figure 5 is a graph illustrating melting profiles for an 18-mer 10 oligonucleotide duplex that is perfectly base-paired (diamonds) and the same oligonucleotide duplex that contains a central mismatch (squares; A/A, position 9). The melting curves are determined in QY low stringency hybridization buffer (Promega, Madison, WI). The percentage single strand (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis).

Figure 6 is a graph showing melting profiles for a set of 19-mer 15 oligonucleotides duplexes that vary in G+C composition from 26% to 73%. All of the duplexes are perfectly base paired. The ΔT_d is 5 $^{\circ}$ C across the entire G+C range. The melting profiles are determined in 3M TMATCA. The % single strand (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis).

Figure 7 is a graph displaying melting profiles for a set of 19-mer 20 oligonucleotides duplexes that vary in G+C composition from 26% to 73%. All of the duplexes are perfectly base paired. The ΔT_d is 4 $^{\circ}$ C across the entire G+C range. The melting profiles are determined in 3M TEATCA. The % single strand (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis).

Figure 8 is a graph illustrating melting profiles for a set of 19-mer 25 oligonucleotide duplexes that vary in G+C composition from 26% to 73%. All of the duplexes are perfectly base-paired. The ΔT_m is 16 $^{\circ}$ C across the entire G+C range. The melting profiles are determined in 0.165M NaCl. The % single strand (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis).

Figure 9 is a graph illustrating melting profiles for an 18-mer 30 oligonucleotide duplex that is perfectly base paired and the same oligonucleotide duplex that contains either a central mismatch (A/A) or abasic substitution at position 9. The melting profiles are determined in GuSCN. The % single strand (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis).

Figure 10 is a graph showing the relationship between molarity and T_d of 35 the data obtained from the melting curves described in Figure 9. The T_d on the y-axis is plotted versus the molarity of GuSCN on the x-axis.

Figure 11 is a graph illustrating melting profiles for an 18-mer oligonucleotide duplex that is perfectly base paired in 1 x PCR buffer or LiTCA over a concentration range of 0.05 M to 0.4 M. The % single strand (y-axis) is plotted versus temperature (x-axis).

5 Figure 12 is a photograph of a 2% agarose gel that shows the presence or absence of an amplicon 381 bp in length. "m", marker; and H17, H14, H11, AB1, dN1, dN2, dN3 and dN6 are the 5' primers used in amplification.

10 Figure 13 is the text scan of a set of arrayed oligonucleotides that when duplexed with probe contain the mismatch indicated in the top row. "C" indicates control probe, "6S" indicates the 6S abasic substituted probe and "8S" indicates the 8S abasic substituted probe. The figure is a compilation of 3 separate filters.

15 Figure 14 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 100 mM 2-methoxyethylamine trifluoroacetate.

Figure 15 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 100 mM diisobutylamine acetate.

20 Figure 16 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 2 M Guanidinium thiocyanate.

25 Figure 17 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 1x PCR buffer.

30 Figure 18 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 1x SSC.

35 Figure 19 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 20% formamide, 10 mM Tris pH 7.6, and 5 mM EDTA with 0.1 % sarkosyl.

Figure 20 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis). The melting solution was 1 M dicyclohexylammonium acetate.

5 Figure 21 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis). The melting solution was 500 mM n-ethylbutylammonium acetate.

10 Figure 22 is a graph showing the difference in T_d between three duplexes, one that is perfectly base-paired and the other two that contains a mismatch or a deoxynebularine substitution. The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis). DMO-2060: 5'-hexylamine-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' (oligonucleotide immobilized on the nylon bead.; DMO-2055: 5'-TEXAS RED-15 TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' (perfect complement); DMO-2058: 5'-TEXAS RED- TGT/GGA/TCA/GGA/AGC/AGG/AGT/ATG-3' (mismatch complement); and DMO-2058-dN: 5'-TEXAS RED-TGT/GGA/TCA/G(deoxynebularine)A/AGC/AGG/AGT/ATG-3' (deoxynebularine mismatch complement). The melting solution was 1 M diisopropylamine acetate. The 20 maximum difference between the 3 melting curves in the T_d or T_m is 6 C. The helical coil transition (HCT) of the true mismatch was 14 C; the HCT for the deoxynebularine mismatch duplex was 14 C and the HCT for the perfectly base paired duplex was 16 C.

25 Figure 23 is a graph showing the difference in T_d between three duplexes, one that is perfectly base-paired and the other two that contains a mismatch or a deoxynebularine substitution. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis). DMO-2060: 5'-hexylamine-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' (oligonucleotide 30 immobilized on the nylon bead.; DMO-2055: 5'-TEXAS RED-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' (perfect complement); DMO-2058: 5'-TEXAS RED- TGT/GGA/TCA/GGA/AGC/AGG/AGT/ATG-3' (mismatch complement); and DMO-2058-dN: 5'-TEXAS RED-TGT/GGA/TCA/G(deoxynebularine)A/AGC/AGG/AGT/ATG-3' (deoxynebularine 35 mismatch complement). The melting solution was 1 M n,n-dicyclohexylamine acetate. The maximum difference between the 3 melting curves in the T_d was 4 C. The helical

coil transition (HCT) of the true mismatch was 15 C; the HCT for the deoxynebularine mismatch duplex was 15 C and the HCT for the perfectly based paired duplex was 15 C.

Figure 24 is a graph showing the difference in T_d between three duplexes, one that is perfectly based-paired and the other two that contains a mismatch or a deoxynebularine substitution. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). DMO-2060: 5'-hexylamine-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' (oligonucleotide immobilized on the nylon bead.); DMO-2055: 5'-TEXAS RED-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' (perfect complement); DMO-2058: 5'-TEXAS RED-TGT/GGA/TCA/GGA/AGC/AGG/AGT/ATG-3' (mismatch complement); and DMO-2058-dN: 5'-TEXAS RED-TGT/GGA/TCA/G(deoxynebularine)A/AGC/AGG/AGT/ATG-3' (deoxynebularine mismatch complement). The melting solution was 1 M n,n-dicyclohexylamine acetate. The maximum difference between the 3 melting curves in the T_d was 4 C. The helical coil transition (HCT) of the true mismatch was 17 C; the HCT for the deoxynebularine mismatch duplex was 17 C and the HCT for the perfectly based paired duplex was 15 C.

Figure 25 is a graph showing the difference in T_d between three duplexes, one that is perfectly based-paired and the other two that contains a mismatch or a deoxynebularine substitution. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). DMO-2060: 5'-hexylamine-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' (oligonucleotide immobilized on the nylon bead.); DMO-2055: 5'-TEXAS RED-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' (perfect complement); DMO-2058: 5'-TEXAS RED-TGT/GGA/TCA/GGA/AGC/AGG/AGT/ATG-3' (mismatch complement); and DMO-2058-dN: 5'-TEXAS RED-TGT/GGA/TCA/G(deoxynebularine)A/AGC/AGG/AGT/ATG-3' (deoxynebularine mismatch complement). The melting solution was 100 mM n,n-dimethylhexylamine acetate. The maximum difference between the 3 melting curves in the T_d was 9 C. The helical coil transition (HCT) of the true mismatch was 15 C; the HCT for the deoxynebularine mismatch duplex was 15 C and the HCT for the perfectly based paired duplex was 15 C.

Figure 26 explains a convention used herein to denote oligonucleotides having a specificity spacer.

DETAILED DESCRIPTION OF THE INVENTION

Prior to setting forth the invention, it may be helpful to an understanding 5 thereof to define certain terms used herein.

As used herein, "hybotrope" refers to any chemical or any mixture of a chemical in an aqueous or organic environment with buffers, chelators, salts and/or detergents that changes the enthalpy of a nucleic acid duplex by at least 20% when referenced to a standard salt solution (0.165 M NaCl, 0.01 M Tris pH 7.2, 5 mM EDTA 10 and 0.1% SDS). That is, the energy content of the nucleic acid duplex is decreased.

The reference oligonucleotide is 5'-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' as the immobilized oligonucleotide and 5'-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' as the solution nucleotide which is typically labeled at the 5'-end with a fluorochrome such as Texas 15 Red. The oligonucleotide duplex (24 nucleotides in length) has a helical to coil transition (HCT) of 25°C or less. The HCT is the difference between the temperatures at which 80% and 20% of the duplex is single stranded. The average minimum slope for a solution to be defined as a hybotrope is the first derivative of the HCT and is equal to 2.4 in units of 1/temperature in degrees C ((80% single strand - 20% single- 20 strand)/25°C).

As used herein, "stringency" is the percentage of mismatched base pairs that are tolerated for hybridization under a given condition.

As used herein, "discrimination" is the difference in T_d between a perfectly base-paired duplex and a duplex containing a mismatch.

25 As used herein, a "discrimination temperature" is a temperature at which a hybridization reaction is performed that allows detectable discrimination between a mismatched duplex and a perfectly matched duplex. As shown herein, a range of temperatures satisfy criteria of a discrimination temperature.

As used herein, an "abasic" residue in an oligonucleotide refers to a 30 compound that approximates the length of a ribofuranose sugar, is covalently attached to neighboring bases (e.g., via phosphodiester or equivalent linkages), and is substituted at the beta anomeric position with a group that does not interact with the base on the opposite strand of a duplex. An abasic residue may be an apurine or apyrimidine structure, an anucleoside structure, or an analogue of a phosphate backbone. The abasic 35 substitution may also consist of a backbone of N-(2-aminoethyl)-glycine linked.

As used herein, a "base analog" in an oligonucleotide refers to a compound that has a ribofuranose sugar and is substituted at the beta anomeric position with a group that has a similar 3-D shape as an A, C, G, T, or U base, but does not hydrogen bond to the base on the opposite strand of a duplex.

5 As used herein, "deoxyNebularine" refers to a 2'-deoxynubularine, which is 9-(beta-D-2'-deoxyribofuranosyl) purine (Eritja et al., *Nucl. Acids Res.* 14:8135, 1986). The molecular formula is C₁₀H₁₂N₄O₄.

10 As used herein, "nucleic acid" or "nucleic acid molecule" refers to any of deoxyribonucleic acids (DNAs), ribonucleic acids (RNAs), oligonucleotides, fragments generated by the polymerase chain reaction, and fragments generated by any of ligation, scission, endonuclease action, and exonuclease action. Nucleic acids can be composed of naturally occurring bases and analogs of naturally occurring bases, or a combination of both. Nucleic acids can be either single stranded or double stranded.

15 As used herein, "T_m" is the temperature at which half the molecules of a nucleic acid duplex are single stranded. T_m is measured in solution, while T_d is measured for the duplex affixed to a solid support, both terms indicate the temperature at which half of a duplex are single stranded.

A. HYBOTROPES

20 As noted above, the present invention provides compositions, including hybotropes, that can change the enthalpy of a nucleic acid duplex (i.e., that can decrease the energy content of the oligonucleotide duplex, so that the cooperativity of the melting processes is increased, as discussed in more detail below). Generally, enthalpy of a duplex in a solution containing a hybotrope is increased at least 20%, and preferably, 30-100% over a duplex in a reference solution comprising 0.165M NaCl.

25 Several consequences flow from increased enthalpy. Importantly, the temperature range over which a duplex melts is decreased, likely due to increased cooperativity of melting. The difference between a hybotropic solution and a hybridization solution used in most molecular biology protocols is illustrated in Figure 4 and Figure 5. In Figure 4, the difference in T_d between a duplex containing a mismatch and duplex which is perfectly base-paired is about 5°C and is clearly distinguished. The hybotrope in Figure 4 is LiTCA. In Figure 5 the difference in T_d between a duplex containing a mismatch and duplex which is perfectly base-paired is less than 2°C and is not distinct. Also, the HCT of the hybotrope in Figure 4 is less than 25°C and the HCT of the SSC-based solution is greater than 25°C.

Because the temperature range of a melt is smaller in a hybotropic solution, there is a greater difference in the T_m of a perfectly complementary duplex and a duplex containing one or more mismatched base pairs (e.g., base pairing other than A:T, G:C, A:U). This property is illustrated in Figure 3 in which an 18 mer duplex 5 perfectly complement or containing a 1 bp mismatch is melted in a solution comprising a hybotrope. As shown, the difference in T_d between the two duplexes is substantial. In general, a hybotrope causes an increase in ΔT_d of $\geq 2^\circ\text{C}$ (e.g., $\geq 2^\circ\text{C}$, $\geq 2.5^\circ\text{C}$, $\geq 3^\circ\text{C}$, $\geq 3.5^\circ\text{C}$, $\geq 4^\circ\text{C}$) over the ΔT_d of the matched and mismatched duplexes in a reference solution (e.g., 0.18M Na⁺). For a 6 to 18 base pair duplex (50% G+C) a hybotrope 10 induces a ΔT_d of $\geq 2^\circ\text{C}$ (e.g., $\geq 2^\circ\text{C}$, $\geq 2.5^\circ\text{C}$, $\geq 3^\circ\text{C}$, $\geq 3.5^\circ\text{C}$, $\geq 4^\circ\text{C}$, $\geq 4.5^\circ\text{C}$, $\geq 5^\circ\text{C}$). for a 19 to 24 base pair duplex, a hybotrope induces a ΔT_d of $\geq 1^\circ\text{C}$ (e.g., $\geq 1^\circ\text{C}$, $\geq 1.5^\circ\text{C}$, $\geq 2^\circ\text{C}$, $\geq 2.5^\circ\text{C}$, $\geq 3^\circ\text{C}$, $\geq 3.5^\circ\text{C}$, $\geq 4^\circ\text{C}$, $\geq 4.5^\circ\text{C}$, $\geq 5^\circ\text{C}$) and for a 25 to 36 base pair duplex, a hybotrope induces a ΔT_d of $\geq 0.5^\circ\text{C}$ (e.g., $\geq 0.5^\circ\text{C}$, $\geq 1^\circ\text{C}$, $\geq 1.5^\circ\text{C}$, $\geq 2^\circ\text{C}$, $\geq 2.5^\circ\text{C}$, $\geq 3^\circ\text{C}$, $\geq 3.5^\circ\text{C}$, $\geq 4^\circ\text{C}$, $\geq 4.5^\circ\text{C}$, $\geq 5^\circ\text{C}$).

15 The melting of a duplex causes a transition from a helical state (duplex) to a coil state (single stranded). The transition, called HCT (helical to coil transition) is readily measured and is expressed in units of temperature. As used herein, HCT is the temperature difference between which a duplex is 80% ($\alpha = 0.8$) and 20% ($\alpha = 0.2$) single-stranded.

20 A hybotrope may be identified as any chemical or any mixture of a chemical in an aqueous or organic environment with buffers, chelators, salts and/or detergents that decreases the enthalpy of a nucleic acid duplex by 20% when referenced to a standard salt solution (0.165 M NaCl, 0.01 M Tris pH 7.2, 5 mM EDTA and 0.1% SDS).

25 The reference oligonucleotide is 5'-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' as the immobilized oligonucleotide and 5'-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' as the solution nucleotide which is typically labeled at the 5'-end with a fluorochrome such as Texas Red. The oligonucleotide duplex (24 nucleotides in length) has a helical to coil transition (HCT) of 25°C or less. The HCT is the difference between the temperatures 30 at which 80% and 20% of the duplex is single stranded.

1. Relationship of Hybotrope to HCT

In Figure 1, the characteristic parameters of a thermal melting profile (helical coil transition) of an oligonucleotide duplex in two different hybridization 35 solutions are presented. The squares represent the melting profile of an oligonucleotide duplex in NaCl based hybridization solution (e.g., SSPE, SSC). 20xSSPE is 173.5g

NaCl, 27.6g NaHPO₄, and 7.4g EDTA at pH7.4 in 1L water. 20xSSC is 175.3g NaCl, 88.2g NaCitrate at pH 7 in 1L water. The diamonds represent the melting profile of the same oligonucleotide duplex in a hybotrope-based hybridization solution, in this case LiTCA (lithium trichloroacetate). T_d is the temperature (°C) at which half of the molecules in a population are single-strand and half of the molecules are double-stranded. The HCT (helical coil transition) is the width of the melting curve from a value of 20% single-strand to 80% single-strand and possesses the unit of temperature (e.g., °C, °K). The stringency factor is the value of the slope (partial derivative) of the helical coil transition at the T_d . Either stringency factor or HCT may be used to identify a hybotrope.

In Table 1, the slope (k) of the linear equation that relates concentration of solute to T_d , the helical coil transition, and the ΔT_d for 9 different hybotropic and hybridization solutions is presented. An 18 bp oligonucleotide duplex was melted in the respective solutions and the values are obtained as described in the examples.

15

Table 1

Hybridization Solution Type	Slope (k)	HCT(°C)	Stringency Factor
LiTCA	19	8	7.5
GuSCN	13	10	6.0
NaSCN	8.5	11	5.4
NaClO ₄	7	12	5.0
KI	5	15	4.0
NaCl	4.5	17.5	3.4
GuCl	3.5	18	3.3
CsTFA	2.5	18	3.3
30% formamide	ND*	20	3.0

* = not determined

Thus, from these data, HCT is inversely proportional to the stringency factor for a given hybridization solution type; the lower the value of HCT, the higher the stringency factor. The HCT increases as the slope of the linear function that relates salt concentration to T_d decreases ($(T_d[\text{salt}] = T_d[0] - k[Cx])$, where $T_d[0]$ is the extrapolated T_d at zero salt concentration, k is the salt specific constant and Cx is the concentration of the salt or hybotrope; see Figure 2).

A hybotrope may be identified as any chemical or any mixture of a chemical in an aqueous or organic environment with buffers, chelators, salts and/or detergents that decreases the enthalpy of a nucleic acid duplex by 20% when referenced to a standard salt solution (0.165 M NaCl, 0.01 M Tris pH 7.2, 5 mM EDTA and 0.1% SDS). The reference oligonucleotide is 5'-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' as the immobilized oligonucleotide and 5'-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' as the solution nucleotide which is typically labelled at the 5'-end with a fluorochrome such as Texas Red. The oligonucleotide duplex (24 nucleotides in length) has a helical to coil transition (HCT) of 25°C or less..

2. Relationship of HCT to Discrimination

Either stringency factor or HCT is related directly to another readily measurable parameter of oligonucleotide duplexes. This parameter, ΔT_d , is the temperature difference between the T_d of an oligonucleotide duplex that is perfectly base paired and the T_d of the same oligonucleotide duplex that contains a mismatch at some position in the duplex (see Figure 3). As shown herein, the temperature difference between a perfectly base paired duplex and a duplex containing a mismatch is a function of the stringency factor (or HCT) of a given hybridization solution or hybotrope. The relationship is expressed as: ΔT_d increases as the stringency factor of a solution increases. In Table 2, this relationship is presented for 18 bp oligonucleotide duplexes. The duplex is melted in the respective hybridization solution and HCT and ΔT_d is determined as described herein.

Table 2

Hybridization Solution Type	Slope (k)	HCT (°C)	ΔT_d (°C)
LiTCA	19	8	7.5
GuSCN	13	10	6.0
NaSCN	8.5	11	5.5
NaClO ₄	7	12	4.5
KI	5	15	3.0
NaCl	4.5	17.5	1.5
GuCl	3.5	18	1.2
CsTFA	2.5	18	1.2
30% formamide	ND*	20	1.5

* = not determined

The data presented in Table 2 show that HCT is inversely proportional to the ΔT_d between a perfectly base paired duplex and a duplex containing a mismatch. 5 That is, either stringency factor or HCT predicts the ability of given hybridization solution to discriminate mismatched duplexes. This aspect of hybotrope-based hybridization is further illustrated in Figures 4 and 5. Figure 4 is a graph showing melting profiles in 2.0 M LiTCA for an 18-mer oligonucleotide duplex that is perfectly base paired (diamonds) and the same oligonucleotide duplex that contains a central mismatch (A/A, position 9). The ΔT_d is 6°C. Figure 5 is a graph showing melting profiles for an 18-mer oligonucleotide duplex in QY low stringency hybridization buffer (Promega, Madison, WI) that is perfectly base paired (squares) and the same oligonucleotide duplex that contains a central mismatch (A/A, position 9). The ΔT_d is 0°C. Therefore, the ΔT_d value relates to the ability of a chemical to discriminate 10 between perfectly base paired duplexes and duplexes that contain a mismatch. The practical utility of this result is discussed below.

In addition, transition enthalpies between a fully base-paired and base stacked double helix to two unpaired and unstacked single strands can be calculated. (Breslauer, K.J., Chapter 15, "Methods for Obtaining Thermodynamic Data on 20 Oligonucleotide Transitions," in *Thermodynamic Data for Biochemistry and Biotechnology*, ed. H. Hinz, Academic Press, New York, NY, 1986.) The difference between a non-cooperative and cooperative transition is expressed in terms of ΔH_{vH} (van't Hoff enthalpy). In a cooperative transition, the value of $(d\alpha/dT)T_d$ is high, and therefore, the ΔH_{vH} is also high. In a non-cooperative transition, the value of $(d\alpha/dT)T_d$

is low, and therefore, the ΔH_{vH} is also low. (The term $(d\alpha/dT)T_d$ is the derivative of the slope of the melting curve at the T_d , α is defined as the % single strand on the ordinate axis.)

In this regard, thermodynamic parameters for two different sets of 5 oligonucleotides (42% G+C; 63% G+C) in three types of hybridization solution are shown in Table 3. The data show that the enthalpy values are inversely related to the values obtained for the temperature range of the thermal coil transition of the duplex (HCT).

Table 3

Solution Type	% G+C	Length (nt)	T_d (°C)	HCT (°C)	ΔH_{vH} (kcal/mol)
2 M LiTCA	42	19 nt	35.5	12	-52.8
2 M TMATCA	42	19	55.4	18	-47.0
3 M TMATCA	42	19	43.0	11.5	-60.7
3 M TMACl	42	19	60.0	15.5	-46.2
2 M LiTCA	63	19	42.0	15	-42.0
2 M TMATCA	63	19	48.0	19.5	-38.6
3 M TMATCA	63	19	47.0	13	-61.8
3 M TMACl	63	19	59.0	17.5	-39.7

10

3. Characterization of a Hybotrope

a. Characteristics of a hybotrope.

As noted herein, a hybotrope is useful within the context of the present invention if it is a solution or is miscible from about 0.05 M to about 10 M in water, 15 other protic, or aprotic solvent. In certain preferred embodiments, the hybotrope does not inactivate polymerases. In other preferred embodiments, the anion part of a hybotrope has a pK_a of less than 2.2.

The chaotrope is a chemical that increases the enthalpy of an oligonucleotide or nucleic acid duplex by at least 20% when referenced to a standard 20 salt solution (*i.e.*, 0.165 M NaCl). Enthalpy is measured by plotting the slope of the thermal transition, α , versus temperature (see Figure 1) and applying the following:

The van't Hoff enthalpy can be obtained from the differentiated equilibrium melting curve (Marky and Breslauer, 1987) by plotting $d\alpha$ versus

temperature. Briefly, thermodynamic data provide a basis for predicting the stability ($\Delta G'$) and temperature- dependent melting behavior (also described here as the helical coil transition (HCT), (ΔH^0)) from the primary sequence of bases in the duplex. We use a thermally induced helical coil transition (from double strand to single strand) to obtain 5 values for the ΔH_{vH} . The analysis of the shape of the helical coil transition is used to calculate the van't Hoff transition enthalpy. As described by Marky and Breslauer, (1987), α is equal to the fraction of single strands in the duplex state. If α is plotted versus temperature the temperature at which α takes the value of 0.5 is defined as the T_d . The equilibrium constant K for any transition can be expressed in the form of α , the 10 van't Hoff enthalpy can be expressed as:

$$\Delta H_{vH} = RT2[d\ln K/dT] \text{ or } \Delta H_{vH} = -R[d\ln K/d(1/T)]$$

To solve the general expression when α takes the value of 0.5 in terms of α the foregoing equation is differentiated and solved for α at the T_d :

$$\Delta H_{vH} = (2 + 2n)RT2(\partial\alpha/\partial T)_{T=T_d} \text{ which can also be written:}$$

$$15 \quad \Delta H_{vH} = (2 + 2n)R(\partial\alpha/\partial(1/T))_{T=T_d}$$

In this series of experiments it is assumed that a bi-molecularity exists where $n=2$ for the preceding equations and therefore the corresponding coefficient is equal to 6. Another assumption employed is that there is no dependence of T_d on concentration since at every temperature increment the concentration of single strands is 20 zero (recall that all unhybridized material is washed away from the solid support prior to the melting process and that at each 5°C temperature increment, the solid support is placed in a fresh solution). For any process at equilibrium, $\Delta G = -RT(\ln K_{eq})$ and $\Delta G = \Delta H - T\Delta S$ it is possible to write $-RT(\ln K) = \Delta H - T\Delta S$.

As has been shown by Gralla and Crothers (Gralla, J., and Crothers, 25 D.M., *J. Mol. Biol.* 73:497-511, 1973) for bimolecular transitions, the full width or half-width of a differentiated melt curve at the half-height is inversely proportional to the van't Hoff transition enthalpy. As suggested, for an equilibrium of the form $nA \leftrightarrow A_n$, the general forms of the van't Hoff equation are:

$$\Delta H_{vH} = B/((1/T_1)-(1/T_2)) \text{ (for the full width at half-height)}$$

$$30 \quad \Delta H_{vH} = B'/((1/T_{max})-(1/T_2)) \text{ (for the upper half-width at half-height)}$$

where T_{max} is the temperature at the maximum, and T_1 and T_2 correspond to the upper and lower temperatures at which value the change in the plotted temperature is equal to one-half of $[(\partial\alpha/\partial(1/T))_{max}]$. For a molecularity of 2, $-B = 10.14$ and $-B' = 4.38$. The detailed derivations are given in Marky and Breslauer, (1987). This approach of 35 measuring the van't Hoff enthalpies is particularly amenable to melting duplexes off

solid supports as all problems associated with baselines and background are completely eliminated.

The equilibrium constant K for a helical transition of a molarity of 2 can be expressed as the extent of α (the fraction of single strand molecules in a duplex).

5 The value of K is usually determined at the T_m of the helical coil transition where $\alpha = 0.5$. This value of the T_m is then extrapolated to some reference temperature (e.g., 298K) using the empirically determined T_m (or T_d) and the calculated van't Hoff enthalpy (assumed to be temperature independent) and the integrated form of the van't Hoff equation:

10
$$\ln[K(T_m)/K(T_{ref})] = \Delta H^0/R(1/T-1/T_m)$$

From the empirically determined value of $K(T_{ref})$, it is possible to determine ΔG^0 for the helical coil transition using the relation $\Delta G^0 = \Delta H^0 - T\Delta S^0$. Since the melting curves described here are concentration independent, the $\ln(K_{T_m}) = 0$ since $K = 1$ at the T_m . Therefore the van't Hoff equation reduces to:

15
$$-\ln K(T) = \Delta H^0/R(1/T-1/T_m),$$

which upon multiplying both sides by RT , provides

$$-RT \ln K(T) = \Delta H^0(1-T/T_m) = \Delta G^0$$

This expression can be used to calculate the transition free energy ΔG^0 at any temperature of interest (T) from the experimentally measured values of T_m and 20 ΔH_{vH} . The corresponding ΔS^0 can be calculated from relation $\Delta G^0 = \Delta H^0 - T\Delta S^0$.

As a result of reducing the HCT, a hybotrope increases the stringency factor of a hybridization solution or solvent, where the stringency factor is the value of the slope (partial derivative) of the helical coil transition at the value of the T_m . As discussed above, the stringency factor can be used to identify a hybotrope.

25 A hybotrope is generally soluble or miscible in water, polar, apolar or organic solvent from about 0.05 to 10 M, or a hybotrope can be composed solely of a polar, apolar or organic solvent.

b. Structure of hybotropes.

30 The term "hybotrope" refers to any chemical or any mixture of a chemical in an aqueous or organic environment with buffers, chelators, salts and/or detergents that changes the enthalpy of a nucleic acid duplex by at least 20% when referenced to a standard salt solution (0.165 M NaCl, 0.01 M Tris pH 7.2, 5 mM EDTA and 0.1% SDS). That is, the energy content of the nucleic acid duplex is decreased.

35 The reference oligonucleotide is 5'-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' as the immobilized

oligonucleotide and 5'-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' as the solution nucleotide which is typically labeled at the 5'-end with a fluorochrome such as Texas Red. The oligonucleotide duplex (24 nucleotides in length) has a helical to coil transition (HCT) of 25°C or less. The HCT is the difference between the temperatures 5 at which 80% and 20% of the duplex is single stranded. The average minimum slope for a solution to be defined as a hybotrope is the first derivative of the HCT and is equal to 2.4 in units of 1/temperature in degrees C ((80% single strand - 20% single-strand)/25°C).

The hybotrope may be a salt selected from LiTCA, RbTCA, GuSCN, 10 NaSCN, NaClO₄, KI, TMATCA TEATCA, TMATBA, TMTCA, TMTBA, TBATCA or TBATBA.

Preferred hybotropes are a salt formed of an anion and a cation, where the anion is selected from acetate, propionate and halogenated versions thereof. The halogen of the halogenated anion is selected from fluorine, chlorine, bromine and 15 iodine, but is preferably fluorine and/or chlorine. The halogenated anion may contain as few as one and as many as three halogen atoms for halogenated acetate. The halogenated propionate may contain as few as one or as many as five halogen atoms. Trichloroacetate and trifluoroacetate are two preferred anions.

The cation is preferably an ammonium ion, not including NH₄. Thus, the 20 cation is a primary, secondary or tertiary ammonium comprising 1-36 carbon atoms, or a quaternary ammonium comprising 4-48 carbon atoms. Preferably, the cation is formed from atoms selected from 2-20 carbon atoms, 0-5 oxygen atoms and 1-5 nitrogen atoms. Thus, the cation substituents, where the groups bonded to the central nitrogen of the ammonium ion are called the "cation substituents" may contain ester, 25 ether, hydroxyl, amine and amide functionality. Preferably, the cation substituents are hydrocarbyl groups, i.e., groups formed entirely of carbon and hydrogen, where hydrocarbyl groups may be saturated or unsaturated, and the carbon atoms of a hydrocarbyl group may be linear, branched or arranged in a cyclic fashion.

A preferred ammonium ion is a quaternary ion of the structure N(R)₄, 30 wherein R is a C₁-C₁₂hydrocarbyl and any two R groups may join together to form a cyclic structure with the nitrogen atom. The phrase "any two R groups may join together to form a cyclic structure with the nitrogen atom" means that the ammonium ion may be heterocyclic in that the central nitrogen atom is part of a cyclic structure. For example, the central nitrogen atom may be the nitrogen atom in piperidine, where 35 this nitrogen atom is also bonded to other R groups. Preferred R groups for the

quaternary ammonium ion are independently selected from C₁-C₁₂alkyl, C₃-C₁₂cycloalkyl and C₇-C₁₂arylalkyl.

Another preferred ammonium ion is a tertiary ion of the structure HN(R)₃, wherein R is a C₁-C₁₂hydrocarbyl and any two R groups may join together to 5 form a cyclic structure with the nitrogen atom. Again, preferred R groups for the tertiary ammonium are independently selected from C₁-C₁₂alkyl, C₃-C₁₂cycloalkyl and C₇-C₁₂arylalkyl.

Yet another preferred ammonium ion is a secondary ion of the structure N(H)₂(R)₂, wherein R is a C₁-C₁₂hydrocarbyl and the two R groups may join together to 10 form a cyclic structure with the nitrogen atom. Again, preferred R groups for the tertiary ammonium are independently selected from C₁-C₁₂alkyl, C₃-C₁₂cycloalkyl and C₇-C₁₂arylalkyl.

Suitable salts include, without limitation, those containing an ammonium cations selected from ethylbutylammonium, 1-methylimidazole, 1-methylpiperidine, 1-15 methylpyrrolidine, 3-methoxypropylamine, triethylamine, bis(2-methoxyethyl)amine, diallylamine, dibutylamine, diisobutylamine, N,N-dimethylaminobutane, N,N-dimethylcyclohexylamine, N,N-dimethylheptylamine, N,N-dimethylhexylamine, triethanolamine, 1-ethylpiperidine, dicyclohexylamine, diisopropylamine, dipropylamine, N,N-dimethylisopropylamine, N-ethylbutylamine, tetraethylammonium, 20 tripropylamine, 2-methoxyethylamine, and N,N-dimethyloctylamine, and the anion is selected from acetate, trichloroacetate and trifluoroacetate.

As used herein, the following terms have the indicated meanings.

Alkyl refers to an aliphatic hydrocarbon radical, —(CH₂)_nCH₃, either branched or unbranched such as methyl, ethyl, N-propyl, iso-propyl, N-butyl, iso-butyl, 25 sec-butyl, tert-butyl, dodecyl or the like.

Aryl refers to a radical derived from an aromatic hydrocarbon by removal of one hydrogen atom such as phenyl, α -naphthyl, β -naphthyl, biphenyl, anthryl and the like.

Arylalkyl, —(CN₂)_n—Ar, refers to an alkyl radical as defined above 30 joined to an aryl radical.

Hydroxyalkyl refers to a radical —(CH₂)_nOH.

Cycloalkane or cycloalkyl refers to a radical of a saturated hydrocarbon in a ring structure such as cyclopropyl, cyclobutyl, cyclopentyl, cyclohexyl, cycloheptyl, adamantyl and the like.

Unless otherwise stated, all number ranges are inclusive of the stated 35 range (e.g., 1 to 5 carbons, includes 1 and 5 carbons).

Halogen refers to chlorine, bromine, iodine or fluorine.

c. Novel hybotropes.

Some of the hybotropes disclosed herein form novel hybridization solutions that improve the specificity of oligonucleotide probes. For example, 5 tetramethylammonium trichloroacetate (TMATCA) and tetraethylammonium trichloroacetate (TEATCA) confer a high level of hybridization stringency. Moreover, these hybotropes neutralize G+C content influence T_d . In the Examples, random 10 oligonucleotide probes (all 19-mers) differing in G+C content from 25% to 73% are shown to possess a T_d within 5°C of each other in the presence of TMATCA (see Figure 6); the average T_d in 3 M TMATCA was 45°C. Similar results are obtained with TEATCA (see Figure 7). As a control, the T_d s of these 19 mers were determined in 3 M TEACl. The resulting differences in T_d was 6°C and the average T_d of the 6 15 oligonucleotides was about 62°C. Furthermore, in 30% formamide, the 6 oligonucleotide probes differed in T_d by 15°C; in 0.165 M NaCl, the range in T_d values was 15°C (see Figure 8); and in 2 M LiTCA, the difference in T_d was about 10°C. Most significantly, however, the HCT in TMATCA ranges from 8°C for the 25% G+C 20 content oligo to 14°C for the 73% G+C oligonucleotide. In contrast, the HCT in TMACl ranges from 12.5°C for the 25% G+C content oligo to 17.5°C for the 73% G+C oligonucleotide. This 4°C to 5°C shift in the HCT of the oligos in the presence of TMATCA results in a significant improvement in the stringency factor of TMATCA compared to TMACl. Thus, TMATCA is a significantly better salt than any previously 25 described solution for conducting oligonucleotide-based assays.

Novel hybridization solutions have also been identified which neutralize 25 the effects of G+C content on the melting behaviour of nucleic acid duplexes. These solutions are in some cases hybotropes and in other cases can be used as PCR buffers or as hybridization solutions which minimize the effects of G+C content on nucleic acid duplexes. These new hybridization solutions, their properties, and their preparation are described in Example 12. Figure 14 is a graph showing the difference in T_d between 30 three duplexes, that vary in G+C content from 27% to 83%. The capture oligonucleotide is a 36-mer (DMO-GC36cap: 5'- hexylamine-GCA/GCC/TCG/CGG/AGG/CGG/ATG/ATC/GTC/ATT/AGT/ATT-3') and three complementary oligos which are labelled with the fluorochrome are DMO-83GC: 5'- Texas Red- CCG/CCT/CCG/CGA/GGC/TGC-3'; DMO-50GC: 5'-Texas Red- 35 AAT/GAC/GAT/CAT/CCG/CCT-3'; DMO-27GC: -Texas Red- AAT/ACT/AAT/GAC/GAT/CAT-3'. The temperature difference between any two T_d s

at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}\text{C}$; x-axis). The melting solution was 100 mM 2-methoxyethylamine trifluoroacetate. The maximum difference between the 3 melting curves in the T_d was 6 $^{\circ}\text{C}$. The helical coil transition of the 27% G+C content was 21 $^{\circ}\text{C}$, 5 50% G+C was 33 $^{\circ}\text{C}$ and for the 83% G+C duplex was 29 $^{\circ}\text{C}$. Note that the helical coil transitions (HCTs) of the 3 different G+C content oligonucleotides is different. This is in contrast to the case with diisobutylamine as shown in Figure 15. Figure 15 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 10 27% to 83% (the same system as described in Figure 14). The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}\text{C}$; x-axis). The melting solution was 100 mM diisobutylamine acetate. The maximum difference between the 3 melting curves in the T_d was 5 $^{\circ}\text{C}$. The helical coil transition of the 27% G+C content was 22 $^{\circ}\text{C}$, 15 50% G+C was 26 $^{\circ}\text{C}$ and for the 83% G+C duplex was 25 $^{\circ}\text{C}$. The helical coil transitions for the three oligonucleotide duplexes are very similar. This is the behaviour that is preferred for use in array hybridizations or polymerase chain reactions.

In Figure 16 the inability of GuSCN to neutralize G+C content is shown. Figure 16 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83% (the same capture and probe oligonucleotides as described in figure 14). The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}\text{C}$; x-axis). The melting solution was 2 M Guanidinium thiocyanate. The maximum difference between the 3 melting curves in the T_d was 16 $^{\circ}\text{C}$. The helical coil transition of the 27% G+C content was 28 $^{\circ}\text{C}$, for the 50% G+C duplex was 30 $^{\circ}\text{C}$ and for 25 the 83% G+C duplex was 32 $^{\circ}\text{C}$. Similar results were obtained with 1x PCR buffer (Figure 17) and 1x SSC buffer (Figure 18). There was also no neutralization of G+C content with 20% formamide (Figure 19).

In contrast to the situation in Figures 17, 18 and 19, Figure 20 shows the melting behaviour of the 3 different G+C oligonucleotide duplexes in 1 M dicyclohexylamine acetate. Figure 20 is a graph showing the difference in T_d between 30 three duplexes, that vary in G+C content from 27% to 83% (same duplexes as described in Figure 14). The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}\text{C}$; x-axis). The melting solution was 1 M dicyclohexylamine acetate. The maximum 35 difference between the 3 melting curves in the T_d or T_m is 3 $^{\circ}\text{C}$. The helical coil transition of the 27% G+C content was 13 $^{\circ}\text{C}$, for the 50% G+C duplex was 17 $^{\circ}\text{C}$ and for

the 83% G+C duplex was 19 C. This is an ideal profile for a hybotrope. In contrast the narrow helical coil transition observed in Figure 20, a much wider HCT is observed with 500 mM n-ethylbutylamine acetate. Figure 21 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83% (the identical duplex system as described in Figure 14). The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 500 mM n-ethylbutylamine acetate. The maximum difference between the 3 melting curves in the T_d is 1 C. The helical coil transition of the 27% G+C content was 22 C, for the 50% G+C duplex was 22 C and for the 83% G+C duplex was 26 C.

The ability of some of the G+C neutralizing buffer to act as hybotropes is illustrated in Figure 22. Figure 22 is a graph showing the difference in T_d between three duplexes, one that is perfectly based-paired and the other two that contains a mismatch or a deoxynebularine substitution. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). DMO-2060: 5'-hexylamine-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' (oligonucleotide immobilized on the nylon bead.); DMO-2055: 5'-TEXAS RED-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' (perfect complement); DMO-2058; 20 5'-TEXAS RED- TGT/GGA/TCA/GGA/AGC/AGG/AGT/ATG-3' (mismatch complement); and DMO-2058-dN: 5'-TEXAS RED-TGT/GGA/TCA/G(deoxynebularine)A/AGC/AGG/AGT/ATG-3' (deoxynebularine mismatch complement). The melting solution was 1 M diisopropylamine acetate. The maximum difference between the 3 melting curves in the T_d is 6 C. The helical coil transition (HCT) of the true mismatch was 14 C; the HCT for the deoxynebularine mismatch duplex was 14 C and the HCT for the perfectly based paired duplex was 16 C. The same situation was observed for 1 M diisopropylamine acetate (Figure 22), 1 M n,n-dimethylcyclohexylamine acetate (Figure 23) and 1 M dicyclohexylamine acetate (Figure 24) and N,N-dimethylhexylamine acetate (Figure 25).

Preferred hybotropes of the present invention include, without limitation, bis(2-methoxyethyl)amine acetate, 1-ethylpiperidine acetate, 1-ethylpiperidine trichloroacetate, 1-ethylpiperidine trifluoroacetate, 1-methylimidazole acetate, 1-methylpiperidine acetate, 1-methylpiperidine trichloroacetate, 1-methylpyrrolidine acetate, 1-methylpyrrolidine trichloroacetate, 1-methylpyrrolidine trifluoroacetate, 2-methoxyethylamine acetate, N,N-dimethylcyclohexylamine acetate, N,N-dimethylcyclohexylamine trifluoroacetate, N,N-dimethylcyclohexylamine, N,N-

dimethylheptylamine acetate, N,N-dimethylheptylamine acetate, N,N-dimethylhexylamine acetate, N,N-dimethylhexylamine acetate, N,N-dimethylisopropylamine acetate, N-ethylbutylamine acetate, N-ethylbutylamine trifluoroacetate, N,N-dimethylaminobutane trichloroacetate, N,N-dimethylisopropylamine trichloroacetate, triethanolamine acetate, triethylamine acetate, triethylamine trichloroacetate, tripropylamine acetate, tetraethylammonium acetate. These compounds or chemicals can be combined with buffers, chelating agents and/or detergents.

10 d. Effect of hybotrope concentration on discrimination.

As shown herein, the discrimination between mismatched oligonucleotides (mutant abbreviated as "mt") and perfectly base-paired oligonucleotides (abbreviated as "wt") is not a function of concentration of a particular hybotrope but rather a function of hybotrope type. Surprisingly, the HCT for the 15 hybotropes LiTCA, GuSCN, GuHCl, and NaClO₄ does not change over about the range of about 0.5 M to about 6.0 M. Moreover, the slope of the mt duplex is always observed to be greater than for wt duplexes (see Figure 9). Furthermore, the difference between the T_m of the wt duplex and the mutant duplex (ΔT_d) is not affected by the concentration of the hybotrope. However, the T_d is directly proportional to 20 concentration (see Figure 10). Because ΔT_d does not change over a wide concentration range for the hybotropic solutions, a wide temperature range can be employed for conducting oligonucleotide-based assays (e.g., 20°C to 80°C). Second, relatively low concentrations (e.g., 0.5 M) of hybotrope may be employed in hybridization assays, including polymerase catalyzed reactions.

25 The approximate concentration range at which a solution of a compound (such as LiTCA) exhibits the characteristics of a hybotropic solution is approximately 0.2 to 0.4 M (Figure 11; Examples).

30 e. Effect of length of duplex.

The length of an oligonucleotide probe (i.e., resultant duplex) has the effect of increasing the T_m as length increases. Due to this relationship, discrimination using a hybotrope is effectively limited to hybridization lengths of 6-40 bases and preferably 6-30 bases.

f. Assays for determining if a compound is hybotropic.

As discussed above, a hybotrope is a chemical that can increase the enthalpy of a nucleic acid duplex by 20% or more when referenced to a standard salt solution. A convenient assay for measuring this increased enthalpy is a thermal transition assay. A hybotrope may be identified as any chemical or any mixture of a chemical in an aqueous or organic environment with buffers, chelators, salts and/or detergents that decrease the enthalpy of a nucleic acid duplex by 20% when referenced to a standard salt solution (0.165 M NaCl, 0.01 M Tris pH 7.2, 5 mM EDTA and 0.1% SDS). The reference oligonucleotide is 5'-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' as the immobilized oligonucleotide and 5'-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' as the solution nucleotide which is typically labelled at the 5'-end with a fluorochrome such as Texas Red. The oligonucleotide duplex (24 nucleotides in length) has a helical to coil transition (HCT) of 25°C or less." Moreover, a suitable hybotrope is soluble in water, other protic solvent or aprotic solvent. Although not required, a hybotrope preferably does not inactivate polymerases when in they are with polymerases and the like in PCR reactions (and the like). Assays for these properties are briefly discussed below.

HCT of an 18-24 mer with a 50% G+C content are readily measured for a given solution. Briefly, an 18-24 mer oligonucleotide and its complement with a 50% G+C are synthesized. The oligonucleotides are dissolved to 2 μ M in the candidate hybotrope solution. The mixture is heated to 85°C (at 0.5°C/min) and then cooled to 10-15°C to allow hybridization. Absorbance versus time is recorded at 260 nm by a UV-VIS spectrophotometer equipped with a thermal programmer. The HCT is determined from a plot of normalized absorbance values (fully annealed = 0% single strand; fully denatured = 100% single strand) versus temperature. A solution in which the temperature difference between 80% and 20% single stranded (HCT) is \leq 25°C is a suitable hybotropic solution within the context of this invention.

Solubility may be measured by making a saturated solution with the respective salt, filtering off undissolved salt, removing the liquid or aqueous material and then determining the weight of the remaining salt.

pK values are measured using standard titration methods.

Polymerase activity in a hybotropic solution may be measured according to the use of the polymerase. For example, in amplification reactions, duplicate reactions with and without the hybotrope are run. The hybotrope does not inactivate the enzyme if 10% of activity is retained.

B. ABASIC, ANUCLEOSIDIC ANALOGS AND DEOXY NEBULARINE RESIDUES

As described herein, an increase in specificity of priming or probing when using synthetic oligonucleotides is accomplished by minimizing the helical coil transition of the respective primer duplex, thereby increasing the stringency factor of the 5 respective sequence. An increased stringency factor of an oligonucleotide decreases the stability of a mismatch and therefore promotes a high fidelity hybridization. Furthermore, increasing the stringency factor or decreasing HCT may also result in an 10 increase in the specificity of priming. One way to increase stringency is to introduce one or more abasic anucleosidic or deoxynebularine residues into one strand of a duplex. Thus, introducing one of these residues leads to a "base pair" that is not 15 hydrogen bonded. In effect, this is analogous to a mismatch and will decrease the T_d and HCT of the respective derived oligonucleotide compared to a perfectly base-paired oligonucleotide that has the same sequence. Although, for the sake of simplicity the oligonucleotides in the examples below incorporate only one type of these residues at a time, combinations such as an abasic and an anucleosidic residue may be utilized.

As noted above, an abasic residue is a compound that approximates the length of a ribofuranose sugar, is covalently attached to neighboring bases and is substituted at the beta anomeric with a group that does not interact [*i.e.*, hydrogen bond] with the base on the opposite strand of a duplex. Abasic residues in oligonucleotides 20 can be introduced by the chemical or enzymatic hydrolysis of the glycosidic bond. The resulting structure is apurinic or apyrimidinic, lacks coding information, and fails to base pair. One abasic residue, the CE phosphoramidite of the tetrahydrofuran derivative, is commercially available (dSPACER, Glenn Research, Sterling, Virginia) along with other "spacer" phosphoramidites (Glenn Research, Sterling, Virginia). 25 Alternatively, an abasic substitution may comprise a backbone of N-(2-aminoethyl)-glycine linked by amide bonds. Unlike native DNA or RNA backbone, this structure has no deoxyribose or phosphate groups.

The typical placement of the abasic site is approximately in the middle of the oligonucleotide. A typical primer has the following configuration: 5'-N₁₀-spacer-30 N₁₀-3'. However, multiple abasic sites may be placed in the oligonucleotide(s) at regular or irregular intervals, depending on the value of HCT to be achieved. Generally, a primer ranges in length from 6 to 40 or from 16 to 30 nt in length and contains from 1 to 5 abasic sites. Thus, abasic sites can be incorporated at a spacing of 3, 4, 5, 6, or 8 nucleotides or incorporated in any combination of nucleotides (or analogues) that base-35 pair with abasic sites. For example, a 6-mer may have one 1 abasic site, an 18-mer, 2 abasic sites, a 24-mer, 3 basic sites, etc. As a general guideline when an

oligonucleotide is used to detect a mutation, the abasic site is preferably not located at the site of the mutation. However, abasic sites may be placed at the site of mutations that are not of interest (e.g., a polymorphism that does not result in a phenotype).

As shown in the table below, introduction of an abasic residue into 5'-hexylamine-TGTGGATCAGCA-spacer-GCAGGAGTATG-3', wherein the spacer is either the C3-spacer or dSPACER from Glenn Research (Sterling, VA, where these two chemicals have the same effect but are chemically distinct), lowers the HCT from 2.5°C to 6°C compared to a normal oligonucleotide, and depending on the solution used.

Table 4

Buffer Type Factor	Oligo Type	HCT (°C)	T _d (°C)	Stringency factor
1X PCR buffer	normal	18		
1X PCR buffer	abasic (dSPACER)	12		
1X PCR buffer	abasic (C3 spacer)	12		
0.5 M TMATCA	normal	14		
0.5 M TMATCA	abasic (dSPACER)	8		
0.5 M TMATCA	abasic (C3 spacer)	8		
2.0 M LiTCA	normal	12.5	44.5	4.97
2.0 M LiTCA	abasic (dSPACER)	10	39	6.37
2.0 M LiTCA	abasic (C3 spacer)	10	39	6.25
3.0 M GuSCN	normal	16	35.5	3.85
3.0 M GuSCN	abasic (dSPACER)	12.5	32	5.24
3.0 M GuSCN	abasic (C3 spacer)	12.5	31	5.31

10

DeoxyNebularine (dN) can also be used to increase the enthalpy of an oligonucleotide duplex. Preferably, deoxyNebularine replaces a G, C, or T base in a probe or primer. Multiple deoxyNebularine sites may be placed in the oligonucleotide(s) at regular or irregular intervals, depending on the value of HCT to be achieved. Generally, a primer ranges in length from 6 to 40, preferably from 16 to 30 bases and contains from 1 to 5 deoxyNebularine sites. A typical primer has the following configuration: 5'-N₁₀- deoxyNebularine -N₁₀-3'. As shown in the table below, introduction of a deoxyNebularine residue into 5'-hexylamine-

TGTGGATCAGCA-dN-GCAGGAGTATG-3' lowers the HCT from 2.5°C to 6°C, depending on the hybridization solution or hybotrope used.

Table 4B

Buffer Type	Oligo Type	HCT*	T _d (°C)	Stringency Factor
1X PCR buffer	normal	18		
1X PCR buffer	deoxyNebularine	12		
1X PCR buffer	deoxyNebularine	12		
0.5 M TMATCA	normal	14		
0.5 M TMATCA	deoxyNebularine	8		
0.5 M TMATCA	deoxyNebularine	8		
2.0 M LiTCA	normal	12	44	5.0
2.0 M LiTCA	deoxyNebularine	10	39	6.3
2.0 M LiTCA	deoxyNebularine	10	39	6.3
3.0 M GuSCN	normal	16	35	3.9
3.0 M GuSCN	deoxyNebularine	12.5	32	5.2
3.0 M GuSCN	deoxyNebularine	12.5	31	5.3

5

The invention thus provides an oligonucleotide comprising a plurality of fragments, each fragment shown schematically by structure (1)

10 wherein,

B₁ B₂ B₃ represents a sequence of at least three nucleotides (and preferably 4-12) as found in wild-type DNA, where "B" represents a base independently selected at each location;

15  represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B₁ and B₅.

The meaning of structure (1) can be understood by reference to Figure 26, where it can be seen that structure (1) corresponds to a sequence of nucleotides wherein at least the base and perhaps more of the nucleotide is missing in the region termed the "specificity spacer". Each specificity spacer occupies no more than a single nucleotide site.

The specificity spacer has steric and chemical properties such that it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

10

Thus, in the structure above, it can be seen that the specificity spacer occupies a single nucleotide site, and does not prevent the "wild-type" nucleotides, *i.e.*, the nucleotides having the standard phosphate-sugar-base group found in naturally occurring oligonucleotides (*e.g.*, DNA, cDNA, RNA) from base-pairing. The wild-type nucleotides are represented by the straight lines terminating in a "B", where "B" represents a standard base selected from adenine, guanine, cytosine, uracil and thymine.

The specificity spacer may or may not hydrogen bond with the nucleotide in the complementary chain (2) with which the chain having structure (1) forms a duplex. Preferably, the specificity spacer cannot hydrogen bond with anything. However, in another preferred embodiment, the specificity spacer can hydrogen bond with the "opposite base" (shown as "B₄" in the duplex of (1) and (2)), but not in the conventional Watson-Crick manner. In fact, if the specificity spacer can hydrogen bond with the base in the complementary chain, then that hydrogen bonding is preferably much weaker than the hydrogen bonding that would occur if the specificity spacer were to bond to the opposite base by standard Watson-Crick base pairing.

A preferred specificity spacer has the formula

30
wherein

Y is selected from oxygen, sulfur, methyl and amino when X is oxygen, or Y is selected from oxygen and sulfur when X is sulfur; and

SSC represents a specificity spacer component having a chain of 2-5 carbon atoms shown in the formula

5

wherein n is 0, 1, 2 or 3. The SSC should not have less than two carbon atoms because that would cause the nucleotides which neighbor the specificity spacer to be too close together to effective hydrogen bond with a complementary oligonucleotide. Likewise, the SSC should not have more than 5 carbons because again that would disrupt the ability of nucleotides in the specificity spacer-containing sequence to hydrogen bond with a complementary sequence. Preferably, the specificity spacer component has a total of 3 or 4 carbons directly separating the two flanking -O-P groups.

15 The 2-5 carbon atoms of the SSC may be substituted with essentially any atoms, so long as the arrangement of those atoms is not such that the specificity spacer completely stops a complementary oligonucleotide chain from hybridizing with the specificity spacer-containing oligonucleotide. Preferred SSCs are either unsubstituted (i.e., are alkylene chains) or are alkylene chains substituted with sterically non-demanding substituents such as halogen, C1-C10hydrocarboxyloxy (a hydrocarbyl group joined to the "2-5 carbon atoms" through an ether oxygen atom), hydroxyl, C1-C5hydrocarbyl and like-sized or smaller groups.

25 The specificity spacer component may contain a five- or six-membered carbocyclic or heterocyclic ring. For instance, the SSC may be a ribose or deoxyribose group as found in a standard nucleotide, however this ribose or deoxyribose is "abasic" in that the purine or pyrimidine base is absent, and is preferably replaced with a hydrogen. A specificity spacer component of this structure may be represented by the formula (2)

30

(2)

wherein n is 1 and X is selected from carbon, oxygen and sulfur, such that any carbon shown in formula (2), including X when it is carbon, may be substituted with hydrogen.

C_1 - C_2 hydrocarbyl, C_1 - C_2 hydrocarbyloxy, a non-hydrogen bonding purine base analog or a non-hydrogen bonding pyrimidine base.

The invention provides oligonucleotides having specificity spacers which may be in solution or may be bound to a solid support. Especially when bound to a solid support, the invention provides compositions in an array form, having a plurality of oligonucleotide sequences, each having specificity spacers.

Each oligonucleotide containing a specificity spacer contains a plurality of such spacers. Thus, specificity spacers preferably constitute 15-60% of the nucleotide positions in an oligonucleotide. However, the specificity spacers are not adjacent to one another, *i.e.*, there is at least one "wild-type" nucleotide located between any two specificity spacers. In fact, all of the specificity spacers in an oligonucleotide preferably are separated by 4-12 "wild-type" nucleotides, and are more preferably separated by 5-8 or 8-12 wild-type nucleotides. The specificity spacers are preferably arranged in a repeating pattern, such that there would be 5 wild-type nucleotides followed by a specificity spacer, followed by 5 more wild-type nucleotides, followed by a specificity spacer, followed by 5 more wild-type nucleotides, etc. At each occurrence in an oligonucleotide chain, the chemical structure of the specificity spacer is independently selected.

Methods of synthesizing oligonucleotides are known to those of skill in the art. In particular, methods of synthesizing oligonucleotides with natural and non-nucleotidic monomers are found in: Oligonucleotide Synthesis: A Practical Approach, Gait, ed., IRL Press, Oxford (1984). The 5'-Dimethoxytrityl-2'-deoxynucleoside-3'-(*N,N*-diisopropyl-2-cyanoethyl)phosphoramidites for the synthesis of standard oligonucleotides are available from Glen Research (Herndon, VA); Beckman Instruments (Brea, CA) or Applied Biosystems (Foster City, CA).

The specificity spacers suitable for direct incorporation into oligonucleotides for use in this invention are commercially as cyanoethyl phosphoramidites from manufacturers like Glen Research, Midland Certified Reagents (Midland, TX), and Clonetech (Palo Alto, CA). Alternatively, other specificity spacers can be prepared from compounds that contain the required diol by a three stage process familiar to those skilled in the art and described in Gait. Stage 1 involves protecting any amine as benzamides or other suitable protecting group. Stage 2 involves protecting one of the hydroxyls, preferably a primary hydroxyl, as a dimethoxytrityl ether using dimethoxytrityl chloride in pyridine. In the third stage the second hydroxyl is converted into a *N,N*-diisopropyl-2-cyanoethyl)phosphoramidite by phosphorylation with *N,N,N,N*-tetraisopropylphosphoramidite and diisopropylammonium tetrazolide.

These phosphoramidites can be used on automated DNA synthesizers available from Beckman, ABI or Perseptive Biosystems.

C. METHODS OF USING HYBOTROPES AND OLIGONUCLEOTIDES CONTAINING AN ABASIC OR ANUCLEOSIDIC RESIDUE

5 As noted herein, a hybotrope may be used in essentially any reaction involving hybridization of a duplex in which the annealed region is from about 6 to about 40 base pairs long. Such reactions include screening for one or few base changes (e.g., genetic screen), DNA sequence analysis by random oligonucleotide hybridization, amplification reactions, RTase polymerization, such as synthesis of cDNA, differential 10 amplification.

As used herein, a "discrimination temperature" is a temperature at which a hybridization reaction is performed that allows discrimination between a mismatched duplex and a perfectly matched duplex. As shown herein, a range of temperatures satisfy criteria of a discrimination temperature. The discrimination temperature ranges 15 from the temperature at which an α value (fraction of single stranded nucleic acid) is 0.2 for a given oligonucleotide duplex (or nucleic acid duplex) containing a mismatch at any place in the duplex, to the temperature at which a value for α equals 0.8 for the same given oligonucleotide duplex (or nucleic acid duplex), but which does not contain a mismatch at any place in the duplex. An α value is the fraction of single stranded 20 nucleic acid at any given temperature generated during the thermal transition of a DNA strand from a double-stranded to a single stranded form. In determining α , the mismatch can be due to any type of modified nucleotide, nucleoside, or derivative thereof. A discrimination temperature is applicable to any given duplex 6 nt to 250 nt 25 in length, of any given G+C content, containing modified or substituted nucleotides or nucleosides, and in which the duplex is composed of deoxyribonucleotides, ribonucleotides, or mixtures of different types of strands. As an example, for an oligonucleotide duplex of 18 nucleotides in length, the critical discrimination temperature (range) would be from 10 to 15°C. The lowest temperature of the discrimination temperature range is dependent on the concentration and type of 30 hybotrope used and can range from 0 to 80°C, preferably from 20 to 50°C.

1. Detection of a Mutation.

Mutations are a single-base pair change in genomic DNA. Within the context of this invention, most such changes are readily detected by hybridization with 35 oligonucleotides that are complementary to the sequence in question. In the system

described here, two oligonucleotides are employed to detect a mutation. One oligonucleotide possesses the wild-type sequence and the other oligonucleotide possesses the mutant sequence. When the two oligonucleotides are used as probes on a wild-type target genomic sequence, the wild-type oligonucleotide will form a perfectly based paired structure and the mutant oligonucleotide sequence will form a duplex with a single base pair mismatch. As shown herein, the resulting two types of duplexes (wild-type and mutant) have different T_d s as a result of a single base pair mismatch in one of the duplexes. For example, a 6 to 7°C difference between the T_d of a wild-type (wt) duplex (perfectly based paired) and duplex containing a mismatch (described above as ΔT_d) is obtained in a hybotrope (LiTCA), but not in standard salt-based hybridization solutions (e.g., SSC). The ΔT_d value for a 30-mer was 6°C, 6.4°C for a 24-mer, and 7°C for a 18-mer.

A "long" oligonucleotide probe (> 18nt) may thus be used for mutation detection in a long polynucleotide target nucleic acid. For this application, a probe that hybridizes only to a single copy portion of the human genome is preferable. A 30-mer can be used to search a collection of 1.15×10^{18} 30 mers (complexity = 3.45×10^{19} nucleotides), a 24-mer can be used to search a collection of 2.81×10^{24} 24 mers (complexity = 6.75×10^{15} nucleotides) and a 18-mer can be used to search a collection of 6.87×10^{10} 10-mers (complexity = 1.23×10^{12} nucleotides). In addition, from an empirical point of view, oligonucleotides work best as probes or primers of eucaryotic DNA or RNA when greater than 23 nt in length.

As discussed above, a 6 to 7°C difference in the T_d of a wild type versus mismatched duplex permits the ready identification or discrimination of the two types of duplexes. To effect this discrimination, hybridization is performed at the T_d of the mismatched duplex in the respective hybotropic solution. The extent of hybridization is then measured for the set of oligonucleotide probes. When the ratio of the extent of hybridization of the wild-type probe to the mismatched probe is measured, a value to 10/1 to greater than 20/1 is obtained. These types of results permit the development of robust assays for mutation detection.

For exemplary purposes, one assay format for mutation detection utilizes target nucleic acid (e.g., genomic DNA) and oligonucleotide probes that span the area of interest. The oligonucleotide probes are greater or equal to 24 nt in length (with a maximum of about 36 nt) and labeled with a fluorochrome at the 3' or 5' end of the oligonucleotide probe. The target nucleic acid is obtained via the lysis of tissue culture cells, tissues, organisms, etc., in the respective hybridization solution. The lysed solution is then heated to a temperature which denatures the target nucleic acid (15-

25°C above the T_d of the target nucleic acid duplex). The oligonucleotide probes are added at the denaturation temperature, and hybridization is conducted at the T_d of the mismatched duplex for 0.5 to 24 hours. The genomic DNA is then collected and by passage through a GF/C (GF/B, and the like) glass fiber filter. The filter is then washed 5 with the respective hybridization solution to remove any non-hybridized oligonucleotide probes (RNA, short oligos and nucleic acid does not bind to glass fiber filters under these conditions). The hybridization oligo probe can then be thermally eluted from the target DNA and measured (by fluorescence for example). For assays requiring very high levels of sensitivity, the probes are concentrated and measured.

10 Other highly sensitive hybridization protocols may be used. The methods of the present invention enable one to readily assay for a nucleic acid containing a mutation suspected of being present in cells, samples, etc., i.e., a target nucleic acid. The "target nucleic acid" contains the nucleotide sequence of deoxyribonucleic acid (DNA) or ribonucleic acid (RNA) whose presence is of interest, 15 and whose presence or absence is to be detected for in the hybridization assay. The hybridization methods of the present invention may also be applied to a complex biological mixture of nucleic acid (RNA and/or DNA). Such a complex biological mixture includes a wide range of eucaryotic and procaryotic cells, including protoplasts; and/or other biological materials which harbor polynucleotide nucleic acid. The method 20 is thus applicable to tissue culture cells, animal cells, animal tissue, blood cells (e.g., reticulocytes, lymphocytes), plant cells, bacteria, yeasts, viruses, mycoplasmas, protozoa, fungi and the like. By detecting a specific hybridization between nucleic acid probes of a known source, the specific presence of a target nucleic acid can be established.

25 A typical hybridization assay protocol for detecting a target nucleic acid in a complex population of nucleic acids is described as follows: Target nucleic acids are separated by size on a gel matrix (electrophoresis), cloned and isolated, sub-divided into pools, or left as a complex population. The target nucleic acids are transferred, 30 spotted, or immobilized onto a solid support such as a nylon membrane or nitrocellulose membrane. (This "immobilization" is also referred to as "arraying"). The immobilized nucleic acids are then subjected to a heating step or UV radiation, which irreversibly immobilizes the nucleic acid. The membranes are then immersed in "blocking agents" which include Dendhart's reagent (Dendhart, *Biochem. Biophys. Res. Comm.* 23:641, 1966), heparin (Singh and Jones, *Nucleic Acids Res.* 12:5627, 1984), and non-fat dried 35 milk (Jones et al., *Gene Anal. Tech.* 1:3, 1984). Blocking agents are generally included in both the prehybridization step and hybridization steps when nitrocellulose is used.

The target nucleic acids are then probed with labeled oligonucleotide probes under conditions described above in hybotrope-based solutions. Probes may be detected by a conjugated enzyme. Unbound enzyme is then washed away and the membrane is immersed in a substrate solution. Signal is then detected by colorimetric means, by 5 fluorescence or by chemiluminescence, depending on substrate type. Alternatively, the probe is directly labeled (e.g., radioactive isotope, fluorescent molecule, mass-spectrometry tags; *see* U.S. Application No. 08/589,250, filed January 23, 1996, chemiluminescent tags and the like).

10 2. DNA sequence analysis.

DNA sequence analysis is conventionally performed by hybridizing a primer to target DNA and performing chain extensions using a polymerase. Specific stops are controlled by the inclusion of a dideoxynucleotide. The specificity of priming in this type of analysis can be increased by including a hybotrope in the annealing 15 buffer and/or incorporating an abasic residue in the primer and annealing at a discriminating temperature.

Other sequence analysis methods involve hybridization of the target with an assortment of random, short oligonucleotides. The sequence is constructed by overlap hybridization analysis. In this technique, precise hybridization is essential. Use 20 of hybotropes or abasic residues and annealing at a discriminating temperature is beneficial for this technique to reduce or eliminate mismatched hybridization. The goal is to develop automated hybridization methods in order to probe large arrays of oligonucleotide probes or large arrays of nucleic acid samples. Application of such technologies include gene mapping, clone characterization, medical genetics and gene 25 discovery, DNA sequence analysis by hybridization, and finally, sequencing verification.

Many parameters must be controlled in order to automate or multiplex oligonucleotide probes. The stability of the respective probes must be similar, the degree of mismatch with the target nucleic acid, the temperature, ionic strength, the 30 A+T content of the probe (or target), as well as other parameters when the probe is short (*i.e.*, 6 to 50 nucleotides) should be similar. Usually, the conditions of the experiment and the sequence of the probe are adjusted until the formation of the perfectly based paired probe is thermodynamically favored over the any duplex which contains a mismatch. Very large scale applications of probes such as sequencing by hybridization 35 (SBH), or testing highly polymorphic loci such as the cystic fibrosis trans-membrane protein locus require a more stringent level of control of multiplexed probes. William

Bains (*GATA* 11:49, 1994), has ascertained that the ability to use multiplexed oligonucleotide probes is generally much more difficult to implement than is suggested by theory. Hybotropes and abasic residues will essentially overcome the limitations in the use of multiplexed probes as presented by Bains.

5 The actual length of an oligonucleotide probe to uniquely prime any natural nucleic acid target is far longer than is predicted by theory. In general, the probability that a given probe is unique is related to the length. Theoretically, the length is 12 to 15 nucleotides when the target is 520 kilobases in length. However, it is shown that a probe needs to be 24 nucleotides in order to possess a 90% probability of
10 being unique. Therefore, using longer "short" probes (*i.e.*, 24-36 nucleotide lengths) in hybridization assays that need to be specific is highly desirable. The methods and compositions presented here substantially aid in the use of long oligonucleotide probes (*i.e.*, 24-36 nucleotide lengths) in terms of discrimination.

15 3. Amplification reactions.

The observation that ΔT_d does not change as a function of concentration of hybotrope has substantial utility for use in DNA, RNA or nucleic acid amplifications based on primer extension by a polymerase (*e.g.*, polymerase chain reaction, *see* U.S. Patent Nos. 4,683,195; 4,683,202; and 4,800,159, cycling probe technology, NASBA).
20 ligation (LCR, ligation chain reaction), and RNA amplification (*see* Lizardi et al., *Bio/Technology* 6:1197, 1988; Kramer et al., *Nature* 339:401, 1989; Lomeli et al., *Clin. Chem.* 35:1826, 1989; U.S. Patent No. 3,786,600). The observation that wt and mt 30-
25 mer oligonucleotides can be distinguished on the basis of thermal melting in 0.5 M LiTCA permits the possibility of a substantial improvement in priming efficiency in
PCR. In its current configuration, the PCR buffer is optimized for the polymerase
rather for specific priming. That is, conditions have evolved since the introduction of
the technique that favor performance of the polymerase over the performance of
specificity of priming with oligonucleotides. Thus, PCR buffer as currently
30 commercially available does not provide or support a high level of stringency of
hybridization of PCR primers.

Commercially available PCR buffers are examined with respect to the melting behavior of 24-mer oligonucleotides in both the wild-type (wt) and mutant (mt) forms. In Table 5, the level of discrimination achieved in PCR buffer versus a low molarity concentration of hybotrope is shown.

Table 5 ΔT_d for PCR buffers and low molarity hybotropes

Solution	Conc.	Oligo Length	HCT*	ΔT_d °	T_d °
PCR buffer	1x	24-mer wt	15		61
PCR buffer	1x	24-mer mt	14	1	60
LiTCA	0.1 M	24-mer wt	12		65.5
LiTCA	0.1 M	24-mer mt	8	4	61.5

* = °C

As shown, the HCT for standard PCR buffer is about 15°C, whereas the HCT for 0.1 M LiTCA is about 12°C. The ΔT_d for the 1x PCR buffer is only 1°C for the 24-mer, whereas the ΔT_d for 0.1 M LiTCA is 4°C. Therefore, priming specificity is significantly improved in 0.1 M LiTCA versus 1X PCR buffer. Higher concentrations of hybridization solutions may also be used (0.1 M LiTCA to 3.0 M LiTCA or 0.1 to 3.0 TMATCA).

Alternatively, priming is performed in a hybotrope solution and chain extension is performed in a separate buffer that supports the polymerase. For example, a solid phase PCR could be employed where the solid phase is moved through two solutions. Priming would occur in some appropriate concentration of LiTCA or TMATCA and then the polymerase chain reaction would take place in a different PCR buffer containing the polymerase. It is also possible to conduct the first few rounds in the amplification in a hybotrope based hybridization solution and conducting the remaining rounds on normal PCR buffer (generally, only the first few rounds are important for specificity).

The use of deoxyNebularine modified oligonucleotides also increases the specificity of priming in the PCR. One deoxyNebularine substitution incorporated into an oligonucleotide reduces the HCT by 2.5°C. Two oligonucleotides probes containing 3 deoxyNebularine sites per 24-mer decrease HCT by 8°C relative to the unsubstituted control. This decrease in the HCT dramatically increases the level of specificity of priming in an amplification reaction (e.g., polymerase chain reaction). This is likely due to the reduction of false or mis-priming during the first few (e.g., 10) cycles of PCR. That is, the enthalpy of the deoxyNebularine substituted oligonucleotide increases relative to the unsubstituted primer, thus increasing the specificity of priming. Within the context of this invention, the primer is preferably 6 to 36 bases in length and contains 1 to 6 deoxyNebularine sites. The sites are preferably separated by 4, 5, 6, 7 or 8 nucleotides and may be separated by up to 12 to 24 nucleotides. The substitutions are

also preferably clustered at the 3' end of the primer to ensure specificity of primer extension by nucleic acid polymerases, which may be, for example, DNA or RNA primers. Moreover, the temperature range over which priming occurs is dramatically reduced when deoxyNebularine-substituted primers are used.

5 As shown in the examples (see Example 8), the temperature range in which amplifications are observed is decreased from about 25°C - 65°C to about 25°C - 35°C. In addition, this decrease is observed for two different DNA polymerases.

10 The results also indicate that the dSpacer substitution prevents the polymerase from "reading through" the abasic site. That is, when the polymerase encounters an abasic residue, chain extension is terminated. However, unlike abasic residues, a deoxyNebularine residue does not terminate chain extension. Although, as noted above, the temperature range over which the amplification range is much reduced compared to non-substituted oligonucleotides. Therefore, deoxyNebularine substituted primers can substantially increase the specificity of a DNA polymerase chain reaction.

15 Furthermore, the combination of an deoxyNebularine site in an amplification PCR primer and a hybotrope salt solution, which promotes a high enthalpy value for the primer duplex, significantly lowers the HCT of the primer duplex. As discussed above, when the HCT decreases, the stringency factor increases and high-discrimination priming of the polymerase chain reaction can take place. These 20 are conditions required for favorable multiplexing PCRs. The term multiplexing refers to the ability to use more than one set of primers in a PCR reaction and generate multiple products or the ability to use more than one target nucleic acid per set of PCR primers.

25 The use of the hybotrope tetramethylammonium trichloroacetate is of particular utility because the dependence of G+C content on T_d (stability) is neutralized. However, other hybotropes of the present invention which may be used in the polymerase chain reaction include, without limitation, bis(2-methoxyethyl)amine acetate, 1-ethylpiperidine acetate, 1-ethylpiperidine trichloroacetate, 1-ethylpiperidine trifluoroacetate, 1-methylimidazole acetate, 1-methylpiperidine acetate, 1-methylpiperidine trichloroacetate, 1-methylpyrrolidine acetate, 1-methylpyrrolidine trichloroacetate, 1-methylpyrrolidine trifluoroacetate, 2-methoxyethylamine acetate, N,N-dimethylcyclohexylamine acetate, N,N-dimethylcyclohexylamine trifluoroacetate, N,N-dimethylcyclohexylamine, N,N-dimethylheptylamine acetate, N,N-dimethylheptylamine acetate, N,N-dimethylhexylamine acetate, N,N-dimethylhexylamine acetate, N,N-dimethylhexylamine acetate, N,N-dimethylisopropylamine acetate, N-ethylbutylamine acetate, N-ethylbutylamine trifluoroacetate, N,N-dimethylaminobutane trichloroacetate.

N,N-dimethylisopropylamine trichloroacetate, triethanolamine acetate, triethylamine acetate, triethylamine trichloroacetate, tripropylamine acetate, tetraethylammonium acetate. These compounds or chemicals can be combined in amplification reaction with divalent cations such as Mg⁺⁺, buffers, detergents, co-factors, nucleotides and their 5 analogs, polymerases and/or ligases. The compounds listed above can be used in concentration ranging from 5 mM to 6 M, preferably from 100 mM to 2.5 M.

D. HYBOTROPES AND ABASIC NUCLEIC ACIDS IN ARRAYS

In the fields of molecular biology and microbiology, it has long been common to employ solid supports having biomolecules immobilized thereon. 10 Immobilization provides various advantages, such as, allowing for multiplexing of samples and ready measurements of tags employed in a large number of signal systems.

Recently, intense attention has focused on creating arrays of biomolecules, and particularly polynucleotides, on a flat solid support. The following publications (and the references cited therein), which are exemplary only, provide 15 general and specific overviews of various utilities for these biomolecular arrays, as well as methods of preparing such arrays: M.D. Eggers et al., *Advances in DNA Sequencing Technology*, SPIE 1891:113-126, 1993; A.B. Chetverin et al., *Bio/Technology* 12:1093-1099, 1994; E.M. Southern, *Nucleic Acids Research* 22:1368-1373, 1994; R.J. Lipshutz et al., *BioTechniques* 19:442-447, 1995; M. Schena, *BioEssays* 18:427-431, 1996; A.P. 20 Blanchard et al., *Biosensors & Bioelectronics* 11:687-690, 1996; M.J. O'Donnell-Malone et al., *Genetic Analysis: Biomolecular Engineering* 13:151-157, 1996; A. Regalado, *Start-Up* 24-30, Oct. 1996; and D. Stipp, *Fortune* 30-41, March 31, 1997.

The advent of large scale genomic projects and the increasing medical use of molecular diagnostics, has prompted the development of large volume 25 throughput methods for screening recombinant DNA libraries representing entire genomes, the performance of large scale DNA sequencing projects, and executing replicative immunological assays, nucleic acid hybridization assays, or polymerase chain reaction assays. The following publications (and the references cited therein), which are exemplary only, provide general and specific overviews of large throughput 30 methods that rely on biomolecular arrays, as well as methods of preparing such arrays: M.D. Eggers et al., *Advances in DNA Sequencing Technology*, SPIE 1891:113-126, 1993; A.B. Chetverin et al., *Bio/Technology* 12:1093-1099, 1994; E.M. Southern, *Nucleic Acids Research* 22:1368-1373, 1994; R.J. Lipshutz et al., *BioTechniques* 19:442-447, 1995; M. Schena, *BioEssays* 18:427-431, 1996; A.P. Blanchard et al., *Biosensors & Bioelectronics* 11:687-690, 1996; M.J. O'Donnell-Malone et al., *Genetic*

Analysis: *Biomolecular Engineering* 13:151-157, 1996; A. Regalado, *Start-Up* 24-30, Oct. 1996; and D. Stipp, *Fortune* 30-41, March 31, 1997.

The need for high throughput methodology has led, in some cases, to a change from a 96-well microtiter dish format, to a 384-well (Maier et al., *J. Biotechnology* 35:191, 1994) or 864-well (Drmanac et al., *Electrophoresis* 13:120, 1992) format, which can also be used in conjunction with robotic devises (see, e.g., Belgrader et al., *BioTechniques* 19:426, 1995; Wilke et al., *Diagnostic Microbiology and Infect. Disease* 21:181, 1995). However, all of these automated techniques require the use of a robotic pin-tool devise that is capable of reproducibly transferring equal volumes of liquid from one arrayed configuration (i.e., 96-well microtiter plate) to another (i.e., 96-spot array on a hybridization filter membrane).

Recently, methods have also been developed to synthesize large arrays of short oligodeoxynucleotides (ODNs) bound to a glass surface that represent all, or a subset of all, possible nucleotide sequences (Maskos and Southern, *Nucl. Acids Res.* 20:1675, 1992). Once such an ODN array has been made may be used to perform DNA sequencing by hybridization (Southern et al., *Genomics* 13:1008, 1992; Drmanac et al., *Science* 260:1649, 1993). The utility of this method of DNA sequencing would be greatly improved if better methods existed for the transfer and arraying of the precise amounts of the biochemical reagents required for the synthesis of large sets ODNs bound to hybridizable surfaces. This would enable greater equality of ODN yield at each position within the array and also increase the nucleotide chain length it is possible to synthesize.

The polymerase chain reaction (PCR) has found wide application to many different biological problems. Two major limitations to the commercial utilization of PCR are the high cost of the reagents and the inability to automate the performance of the process. Reagent costs can be lowered if the total volume of each reaction can be decreased, allowing a concomitant decrease in DNA polymerase and nucleotides. An accurate and reliable means to array small volumes of reagents using a robotically controlled pin tool could help solve both of these PCR problems.

The combination of hybotropes and modified oligonucleotide probes described in this application will permit the useful multiplexing of probes and "capture" oligonucleotides in the array format. Hybotropes that neutralize the G+C content effect on T_m or T_d are especially useful in the application and use of array technology. In traditional hybridization solutions the difference in T_m or T_d when the G+C content is varied from 20% to 80% is generally 12 to 16°C. Therefore is it impossible to maintain the ideal hybridization temperature which is 1 to 8 degrees below the T_m of the

respective oligonucleotide duplex as the G+C content is varied. Solutions (hybotropes) which neutralize the effect of G+C on T_m or T_d permit the useful multiplexing of probes. Hybotropes such as bis(2-methoxyethyl)amine acetate, 1-ethylpiperidine acetate, 1-ethylpiperidine trichloroacetate, 1-ethylpiperidine trifluoroacetate, 1-methylimidazole acetate, 1-methylpiperidine acetate, 1-methylpiperidine trichloroacetate, 1-methylpyrrolidine acetate, 1-methylpyrrolidine trichloroacetate, 1-methylpyrrolidine trifluoroacetate, 2-methoxyethylamine acetate, N,N-dimethylcyclohexylamine acetate, N,N-dimethylcyclohexylamine trifluoroacetate, N,N-dimethylcyclohexylamine, N,N-dimethylheptylamine acetate, N,N-dimethylheptylamine acetate, N,N-dimethylhexylamine acetate, N,N-dimethylisopropylamine acetate, N-ethylbutylamine acetate, N-ethylbutylamine trifluoroacetate, N,N-dimethylaminobutane trichloroacetate, N,N-dimethylisopropylamine trichloroacetate, triethanolamine acetate, triethylamine acetate, triethylamine trichloroacetate, tripropylamine acetate, tetraethylammonium acetate are useful in array formats.

A number of genetic diseases are caused by single, or a limited set, of mutations due to founder effects or advantages to heterozygous carriers. There is an increasing clinical interest in monitoring sequence variants associated with, for example, altered metabolism of drugs or serving as genetic markers in forensic medicine, and in the diagnosis of infectious disease, identification of drug-resistant variant strains may require distinction between similar sequence variants.

The solutions described herein are used to increase the specificity of priming in the PCR. There are several options in terms of a mechanism in which the specificity of the priming step can be improved. The first is a through the use of a solid support to which one of the PCR primers is (covalently) attached. The solid support can take many forms such as beads, membranes, etc. The priming step can take place in the hybotrope and then the solid support can be washed and moved into a solution that supports the polymerase chain extension. The solid support is then moved back into the nesstrope for the priming reaction and the cycle is repeated. The cycling of the solid support between the two different solutions only has to occur to a limited number of times (1-15 cycles) after which time the traditional amplification cycle in a standardized PCR buffer can be allowed proceed. Alternatively, the target nucleic acids of interest are moved between the priming solution and the polymerase extension reaction solution using electric fields (*i.e.*, electrophoresis).

The use of hybotropes and/or abasic or anucleosidic oligonucleotide probes can be used to increase the specificity and efficiency of isothermal applications

of polymerases to the amplification of nucleic acid sequences. Applications of isothermal conditions for using nucleic acid polymerases include nucleic acid sequencing, genotyping, mutation detection, oligonucleotide ligation assays, mutation detection, and the like.

5

The following examples are offered by way of illustration, and not by way of limitation.

EXAMPLES

EXAMPLE 1

PREPARATION, PROPERTIES, AND USES OF NOVEL HYBOTROPES

5

A novel hybotrope is synthesized which demonstrates properties not previously described for a salt solution. Tetramethyl ammonium- and tetraethyl ammonium-trichloroacetate are synthesized by neutralizing tetramethyl ammonium- and tetraethyl ammonium-hydroxide with trichloroacetate to pH 7.0 to pH 8.5, 10 depending upon the application. The resulting salt solution is then dried under vacuum to complete dryness and the mass is determined. The salt is then dissolved in water to a final concentration of 0.5 to 3.0 M. The resulting salt solution is then buffered with a buffer such as Tris-HCl, pH 7.0-8.5, and detergents, such as sarkosyl, are added to about 0.1%, and optionally EDTA is added to 0.5 to 5 mM.

15 These hybotropes possess the property of neutralizing the differences in G+C and A+T base-pairing strength while simultaneously lowering the T_d and ΔT_d , increasing ΔT_d . In the table below the characteristics of the novel TEATCA and TMATCA hybotropes.

20 25% G+C content: 5'-AAATAATTCAAGGGTCAAAA-3'
36% G+C content: 5'-CTGTCGTAGGTAAATAACT-3'
42% G+C content: 5'-AAAAAGTGGGGAAGTGAGT-3'
57% G+C content: 5'-GTGTTAACCTCCGCTCCTC-3'
63% G+C content: 5'-GGCGTAGGTCTGTCGTGCT-3'
25 73% G+C content: 5'-GGTGTGGGTCCCGTCGTGCC-3'

The following T_d s are obtained in the hybridizations described below:

Table 6

Solution Type	Length of Probe	G+C Content	T_d	HCT
3 M TEATCA	19-mer	25%	38.0	7.5
3 M TEATCA	19-mer	36%	38.5	10
3 M TEATCA	19-mer	42%	39	11.5
3 M TEATCA	19-mer	57%	40	12
3 M TEATCA	19-mer	63%	41	13
3 M TEATCA	19-mer	73%	42	14
3 M TMACI	19-mer	25%	61	12.5
3 M TMACI	19-mer	36%	62	14
3 M TMACI	19-mer	42%	60	15.5
3 M TMACI	19-mer	57%	65	17
3 M TMACI	19-mer	63%	59	17.5
3 M TMACI	19-mer	73%	59	17.5
3 M TMATCA	19-mer	25%	44.5	8
3 M TMATCA	19-mer	36%	45.5	10
3 M TMATCA	19-mer	42%	43	11.5
3 M TMATCA	19-mer	57%	48.5	12
3 M TMATCA	19-mer	63%	47	13
3 M TMATCA	19-mer	73%	48.5	14
2 M TMATCA	19-mer	25%	43	15
2 M TMATCA	19-mer	36%	44.5	17
2 M TMATCA	19-mer	42%	44.5	18
2 M TMATCA	19-mer	57%	53	19.5
2 M TMATCA	19-mer	63%	48	19.5
2 M TMATCA	19-mer	73%	52	19
30% formamide	19-mer	25%	25	20
30% formamide	19-mer	36%	27.5	20
30% formamide	19-mer	42%	29	20
30% formamide	19-mer	57%	40	21
30% formamide	19-mer	63%	37.5	22
30% formamide	19-mer	73%	40	23

The data in Table 6 clearly indicate a decrease in the helical coil transition in solutions containing 3 M TMATCA or 3 M TEACl compared to the control solution which is TMACL. An average decrease of 3.5°C is observed for 5 solutions containing 3 M TMATCA or 3 M TEACl compared to the control solution which is TMACL. Also, formamide has a surprisingly high value for the helical coil transition, which ranges from 20 to 23°C depending on the G+C value. Also shown is the concentration dependence of the ability of a TMATCA solution to neutralize G+C content. At 2 M, TMATCA is neither able to neutralize G+C content or reduce the 10 HCT. This property is unique as no other hybotrope displays a concentration dependence.

EXAMPLE 2

DETERMINATION OF THE MELTING TEMPERATURE OF OLIGONUCLEOTIDE DUPLEXES IN 15 VARIOUS HYBOTROPE AND NON-HYBOTROPE BASED HYBRIDIZATION SOLUTIONS.

This example describes the determination of the T_m of wild type and mutant oligonucleotides when hybridized to a target nucleic acid. It is shown that hybotrope based hybridization solutions allow the detection of single base pair 20 mutations in a nucleic acid target with a probe up to a 30 nucleotides in length.

Solutions and Reagents

Filter wash (FW) is 0.09 M NaCl, 540 mM Tris pH 7.6, 25 mM EDTA. SDS/FW is FW with 0.1% sodium dodecyl sulfate (SDS). Hybridization solutions 25 contain the text specified concentration of hybotrope 2% N-lauroylsarcosine (sarcosyl), 50 mM Tris pH 7.6 and 25 mM EDTA. Formamide hybridization solution contains 30% formamide, 0.09 M NaCl, 40 mM Tris-HCl pH 7.6, 5 mM EDTA and 0.1% SDS. GuSCN is purchased from Kodak (Rochester, NY). GuCl, lithium hydroxide, trichloroacetic acid, NaSCN, NaClO₄, and KI, are purchased from Sigma (St. Louis, 30 MO). Rubidium hydroxide is purchased from CFS Chemicals (Columbus, OH). CsTFA is purchased from Pharmacia (Piscataway, NJ).

Preparation of LiTCA, TMATCA and TEATCA

LiTCA and TMATCA, and TEATCA are prepared by the dropwise titration of a 3 N solution of LiOH, TEAOH and TMAOH respectively, with

trichloracetic acid (100% w/v, 6.1 N) to pH 7.0 on ice with constant stirring. The salt is evaporated to dryness under vacuum, washed once with ether and dried.

Oligonucleotide Synthesis

10 Oligonucleotides are synthesized on a commercial synthesizer using standard cyanoethyl-N,N-diisopropylamino-phosphoramidite (CED-phosphoramidite) chemistry. Amine tails are incorporated onto the 5'-end using the commercially available N-monomethoxytritylaminohex-6-yloxy-CED-phosphoramidite. Alternatively, oligonucleotides are commercially purchased.

Preparation of Nylon Bead Supports (ODN-Bead)

15 ODN (oligonucleotide)-beads (3/32nd inch diameter) are prepared as previously described (Van Ness et al., *Nucl. Acids Res.* 19:3345, 1991). The ODN-beads contain 0.01 to 1.2 mg/bead of covalently immobilized ODN.

Determination of T_d and T_{opt} Values Using ODN-Beads in Various Hybridization Solution Containing Hybotropic Salts

20 15 To label the probe oligonucleotides, amine ODNs are reacted with amine-reactive fluorochromes. The derived ODN preparation is divided into 3 portions and each portion is reacted with either (a) 20-fold molar excess of Texas Red sulfonyl chloride (Molecular Probes, Eugene, OR), with (b) 20-fold molar excess of Lissamine sulfonyl chloride (Molecular Probes, Eugene, OR), or (c) 20-fold molar excess of fluorescein isothiocyanate. The final reaction conditions consist of 0.15 M sodium borate at pH 8.3 for 1 hour at room temperature. The unreacted fluorochromes are removed by size exclusion chromatography on a G-50 Sephadex column.

25 20 For the determination of ODN/ODN T_d from the ODN-bead, fluorescently-labeled ODN is incubated in various hybridization solutions with a complementary ODN immobilized on ODN-beads. From 5 to 5000 ng of ODN are hybridized in 300-400 μ l volumes at various temperatures (19-65°C) for 5-30 minutes with constant agitation. The beads are washed with 3 x 1 ml of the respective hybridization solution, and then once with the respective melting solution at the starting temperature of the melting process. The beads in 300-400 μ l of the respective melting solution are then placed in a 0-15°C water bath. At 5 minute intervals, the temperature is raised 5°C, the solution decanted into a well of a microtiter plate, and fresh solution (5°C below the next increment) is added to the beads. The "melting" or duplex

dissociation is conducted over a temperature range of 15°C to 95°C. Fluorescence is measured with a commercial fluorescence plate reader.

To calculate the T_d , cumulative counts eluted at each temperature are plotted against temperature. The temperature at which 50% of the material is 5 dissociated from the bead is the T_d .

For the determination of RNA/ODN or DNA/ODN T_d mems from nylon membranes (Schleicher & Schuell, Keene, N.H.), ^{32}P -labeled ODN (3'-labeled with terminal transferase) is incubated with 0.5 cm² pieces of membrane, in text-specified hybridization solutions. For the (non-covalent) immobilization of genomic DNA onto 10 nylon membranes, purified DNA is denatured in 0.3 M NaOH at 20°C for 10 minutes. An equal volume of 2 M ammonium acetate is added and the sample was applied to Nytran membranes assembled in a slot blot apparatus. RNA was denatured in 4.6 M formaldehyde-6 x SSC (0.9 M NaCl, 90 mM sodium citrate) for 15 min. at 60°C and applied to the membranes as above. After immobilization of the nucleic acids, the 15 filters were baked at 80°C for 2 hours, then stored dry at ambient temperature. The hybridizations and dissociations were then performed as described above for the nylon bead solid supports.

To determine the T_{opt} ODN (the temperature at which the maximum rate 20 of hybridization of target nucleic acid to ODNs occurs, under near stringent to stringent conditions (-20 to -5°C below the T_d)), complementary ^{32}P -labeled ODN is hybridized (to the $C_0t_{\text{1/2}}$) to either covalently immobilized ODN sequences on the ODN-bead as described above, or in a sandwich assay format when RNA is used as the target nucleic acid. The hybridizations are performed over a 40°C range (+ or -20°C around the T_d of the respective duplex in 5°C increments). The extent of hybridization is then measured 25 as a function of temperature at the $C_0t_{\text{1/2}}$ of the respective hybridization.

Spectroscopic Thermal Denaturation

Thermal transitions determined in solution (T_m) are recorded at 260 nm using a Gilford System 2600 UV-VIS spectrophotometer equipped with a Gilford 2527 Thermo-programmer. ODNs (2 mM/strand) are dissolved in the respective 30 hybridization or melting solutions. The ODN mixtures were heated to 85°C, then cooled to 10-15°C to allow hybridization. The samples were slowly heated to 85°C employing a temperature increase of 0.5°C/min. Absorbance versus time is recorded, and the first derivative is computed automatically. The T_m values are determined using the first derivative maxima.

Oligonucleotides

The following oligonucleotides are used to measure the difference in T_d between a wild type oligonucleotide and a mutant oligonucleotide. The wild type oligonucleotide represents fully and perfectly base-paired duplex and a mutant oligonucleotide represents a single base pair mismatch (generally in the middle of the oligonucleotide).

The sequence of the "capture" oligonucleotide is 5'-GTCATACTCCTGCTTGCTGATCCACATCTG-3'. The sequence of the wild type 30-mer is 5'-CAGATGGGTATCAGCAAGCAGGAGTATGAC-3', the sequence for the wild type 24-mer 5'-ATGGGTATCAGCAAGCAGGAGTAT-3', the sequence for the wild type 18-mer 5'-GGTATCAGCAAGCAGGAG-3'. The sequence of the mutant 30-mer is 5'-CAGATGGGTATCAGGAAGCAGGAGTATGAC-3', the sequence for the mutant 24-mer 5'-ATGGGTATCAGGAAGCAGGAGTAT-3', the sequence for the mutant 18-mer 5'-GGTATCAGGAAGCAGGAG-3'.

The helical coil transition of an oligonucleotide or nucleic acid duplex can be measured by essentially an adaptation of methods previously described by Martinson (*Biochemistry* 12:145-165, 1973) for the thermal elution of DNA or RNA duplexes or hybrids from hydroxylapatite. For the determination of the helical coil transition from a solid support, fluorescently-labeled oligonucleotide (ODN) was incubated in various hybridization solutions with a complementary ODN immobilized on ODN-beads. From 5 to 5000 ng of ODN were hybridized in 300-400 μ l volumes at various temperatures (19-65°C) for 5-30 minutes with constant agitation. The beads were washed with 3 x 1 ml of the respective hybridization solution, and then once with the respective melting solution at the starting temperature of the melting process. The beads in 300-400 μ l of the respective melting solution were then placed in a 0-15°C water bath. At 5 minute intervals, the temperature was raised 5°C, the solution decanted into a well of a microtiter plate, and fresh solution (5°C below the next increment) was added to the beads. The "melting" or duplex dissociation was conducted over a temperature range of 15°C to 95°C. Fluorescence was measured with a commercial fluorescence plate reader. To calculate the T_d , cumulative counts eluted at each temperature were plotted against temperature. The temperature at which 50% of the material had been dissociated from the bead was taken as the T_d . The helical coil transition is defined as the temperature at which a value of a equals 0.2 for a given oligonucleotide duplex (or nucleic acid duplex, containing or not containing a mismatch at any place in the duplex) to the temperature at which a value for a equals 0.8 for the same given oligonucleotide duplex (or nucleic acid duplex).

The following T_g s are obtained in the hybridizations described below:

Table 7

Solution Type	Length of Probe	T_g (Mutant) (°C)	T_g (Wild Type) (°C)	ΔT_g (°C)	HCT (°C)
2.5 m LiTCA	30-mer	27	33	6	13/14
2.5 m LiTCA	24-mer	25.5	32	6.5	13/14.5
2.5 m LiTCA	18-mer	24	31	7	9/14
2.0 m LiTCA	30-mer	42	47	5	13.5/16
2.0 m LiTCA	24-mer	38	44	6	14/15
2.0 m LiTCA	18-mer	37	43	6	14.5/16.5
3.0 m GuSCN	30-mer	37	42.5	5.5	13.5/17.5
3.0 m GuSCN	24-mer	34.5	41	6.6	12.5/17
3.0 m GuSCN	18-mer	33.5	40.5	7	14.5/15
3.0 m GuHCl	30-mer	55.5	60	4.5	16/21
3.0 m GuHCl	24-mer	52.5	58	5.5	15/20
3.0 m GuHCl	18-mer	50	57	7	18/20
Rapid Hybe	30-mer	80	80	0	na*
Rapid Hybe	24-mer	80	80	0	na
Rapid Hybe	18-mer	68	70	2	18/23
5x SSC	30-mer	72.5	72.5	0	18/18
5x SSC	24-mer	69	70	1	18/18

Solution Type	Length of Probe	T _d (Mutant) (°C)	T _d (Wild Type) (°C)	ΔT _d (°C)	HCT (°C)
5x SSC	18-mer	67	72	5	16/18
Promega QY	30-mer	80	80	0	na
Promega QY	24-mer	80	80	0	na
Promega QY	18-mer	62	65	3	20/23

* na indicates not applicable or too large to accurately determine.

The data indicate that the hybotropic solutions (LiTCA, GuSCN and GuHCl) permit the detection of a single base-pair mismatch in a 24-mer and 30-mer probe whereas the detection of a single base-pair mismatch in standard hybridization 5 solutions (Rapid Hybe, Promega QY or 5x SSC) is not possible.

A similar experiment is performed for the 24-mers described above in a series of hybridization solutions.

Table 8

Hybridization Solution Type	Slope ([..], k)	HCT	ΔT _d
LiTCA, 3 M	19	8 C	7.5 C
GuSCN, 3 M	13	10	6.0
NaSCN, 3 M	8.5	11	5.5
NaClO ₄ , 3 M	7	12	4.5
KI, 3 M	5	15	3.0
NaCl, 0.165 M	4.5	17.5	1.5
GuCl, 3 M	3.5	18	1.2
CsTFA, 2M	2.5	18	1.2
30% formamide	ND	20	1.5

10

T_d(wt) is the T_d of a perfectly base-paired oligonucleotide duplex and T_d(mt) is the T_d of a oligonucleotide duplex containing a single mismatch. The values are for a 24-mer duplex of sequence described in Example 1. From the data presented

in the table above, the stringency factor is directly proportional to the difference between a perfectly base paired duplex and a duplex containing a mismatch. That is, the stringency factor predicts the ability of given hybridization solution to discriminate mismatched duplexes.

5

EXAMPLE 3
EFFECT OF CONCENTRATION OF SALT OR HYBOTROPE ON HCT AND T_d .

The discrimination between mismatched oligonucleotides (mutant abbreviated as "mt") and perfected based-paired oligonucleotides (abbreviated as "wt") is not a function of concentration of a particular hybotrope but rather a function of hybotrope type. HCT is defined as the temperature range over which a duplex melts during a melting process under defined conditions. To calculate HCT, the temperature at which 80% of the duplexes are melted is subtracted from the temperature at which 20% melting is observed. Surprisingly, for the hybotropes LiTCA, GuSCN, GuHCl, NaClO₄, the HCT does not change over about the range of 0.5 M to about 6.0 M. The slope of the mt duplex is always observed to be greater than for wt duplexes (see Table 8). Another parameter which does not change as a function of concentration is the difference between the T_d of the wt duplex and the mutant duplex (ΔT_d). The T_d of the mt and wt duplexes is observed to be strictly dependent on concentration in a precisely linear relation. In Table 9, the HCT and T_d for mt and wt 30-mer duplexes and mt and wt 18-mers are presented.

The effect of concentration and hybotrope type on HCT, ΔT_d , and T_d .

Table 9

Hybotrope	Conc.	Oligo Length	HCT	ΔT_d	T_d
GuSCN	0.5 M	24-mer wt	12.5 C		70 C
GuSCN	0.5 M	24-mer mt	10.0 C	4.0 C	74
GuSCN	1.0 M	24-mer wt	12.5 C		65
GuSCN	1.0 M	24-mer mt	10.0 C	3.5 C	68.5
GuSCN	2.0 M	24-mer wt	12.5 C		52
GuSCN	2.0 M	24-mer mt	10.0 C	4.0 C	56
GuSCN	2.5 M	24-mer wt	12.5 C		46.5
GuSCN	2.5 M	24-mer mt	12.5 C	3.5 C	50

The data from Table 9 is graphically represented in Figure 9.

Because ΔT_d does not change over a wide concentration range for the hybotropic solutions described above, a wide temperature range can be employed for 5 conducting oligonucleotide-based assays (i.e., 20 to 80°C). In addition, relatively low concentrations (e.g., 0.5 M) of oligonucleotide can be employed in assays and polymerase based assays.

EXAMPLE 4

10 DETECTION OF A SINGLE BASE-PAIR MISMATCH ON A SOLID PHASE.

This example describes the detection of a single-base pair mismatch in an immobilized probe using complementary fluorescently labeled oligonucleotides. The set of probe oligonucleotides consists of one probe which forms perfect base-pairing and one oligonucleotide which contains the mismatch when hybridized. The 15 two oligonucleotides are labeled with different fluorochromes, and after hybridization is allowed to occur at the T_d of the mismatch, the ratio of hybridized fluorochromes is determined.

	A	"target"	oligonucleotide	(DMO501: 5'-
20	TTGATTCCCAATTATGCGAAGGAG-3')			
				ODN-beads (3/32nd inch diameter) were prepared as previously described (Van Ness et al., <i>Nucl. Acids Res.</i> 19:3345, 1991). The ODN-beads contained 0.01 to 1.2 mg/ bead of covalently immobilized ODN. DMO578 is the complement to DMO501 (perfect complement). DMO1969 is the complement to DMO501 with a G-->T change at
25				position 11. DMO1971 is the complement to DMO501 with a A-->T change at position 12. Each probe oligonucleotide was labeled with either BODIPY, TAMRA or Texas Red. Hybridization reactions were assembled in 3 M GuSCN, 0.01 M Tris pH 7.6, 5 mM EDTA at 50 ng/ml respective probe. Equal molar ratios of each probe type were used in each hybridization in the presence of 3 solid supports per tube.
30				Hybridizations are performed at 42°C for 30 minutes with constant agitation. The beads were washed twice with 3 M GuSCN at 42°C and then with SDS/FW 5 times.

To denature the probe oligonucleotide, the solid supports are placed in 200 μ l TE (TE is 0.01 M Tris, pH 7.0, 5 mM EDTA). The mixture is incubated for 10 minutes at 100°C. Fluorescence is measured in a black microtiter plate. The solution is 35 removed from the incubation tubes (200 microliters) and placed in a black microtiter plate (Dynatek Laboratories, Chantilly, VA). The plates are then read directly using a

Fluoroskan II fluorometer (Flow Laboratories, McLean, VA) using an excitation wavelength of 495 nm and monitoring emission at 520 nm for fluorescein, using an excitation wavelength of 591 nm and monitoring emission at 612 nm for Texas Red, and using an excitation wavelength of 570 nm and monitoring emission at 590 nm for 5 lissamine or TAMRA.

The results are as follows:

Table 10

Probe Mix	Fluorochrome ratio in hybridization mix	Fluorochrome ratio after denaturing
578TR/578BD	1.9/1	1.9/1
578TR/1969BD	2.0/1	25/1
578TR/1971TA	0.025/1	0.58/1
578BD/1971TA	0.014/1	0.48/1

10 The results indicate that there is no effect of the fluorochrome on the hybridization as indicated in line 1 that Texas Red (TR) 578 oligonucleotide and 578-BD (BODIPY) competed evenly for hybridization to the immobilized target since the ratio of labels did not change after hybridization. There is an average of a 20-fold enrichment of perfectly based probes over the mismatched probes in GuSCN allowing certain detection of base-pair mismatches.

15

EXAMPLE 5

DETERMINATION OF THE HELICAL COIL TRANSITIONS IN PCR AND LOW MOLARITY HYBOTROPE SOLUTIONS.

20 The observation that ΔT_m does not change as a function of concentration of hybotrope has substantial utility for uses in DNA, RNA or nucleic acid amplifications based on primer extension by polymerases (*i.e.*, polymerase chain reaction). The observation that mismatched probes as long as 30-mer oligonucleotides can be distinguished on the basis of thermal melting in 0.5 M LiTCA, permits the 25 possibility of a substantial improvement in priming efficiency in the PCRs. In its current configuration, the PCR buffer is optimized for the polymerase rather for specific priming.

Commercially available PCR buffers were examined with respect to the melting behavior of 18-mers, 24-mers and 30-mers in both the wild-type (wt) and mutant (mt) forms. In Table 11, the level of discrimination achieved in PCR buffer versus a low molarity concentration of hybotrope is presented.

5

Table 11: ΔT_d for PCR Buffers and Low Molarity Hybotropes

Hybotrope	Conc.	Oligo Length	HCT	ΔT_d	T_d
PCR buffer	1x	24-mer wt	15 C		61 C
PCR buffer	1x	24-mer mt	14 C	1C	60 C
LiTCA 0.1 M		24-mer wt	12 C		65.5
LiTCA 0.1 M		24-mer wt	8 C	4 C	61.5

10 Note that the HCT for standard PCR buffer is about 15°C whereas the HCT for 0.1 M LiTCA is about 12°C. The ΔT_d for the 1x PCR buffer is 1°C for the 24-mer whereas the ΔT_d in 0.1 M LiTCA is 4°C. Thus, priming specificity is significantly improved in a 0.1 M LiTCA versus 1X PCR buffer.

15

EXAMPLE 6

INTRODUCTION OF AN ABASIC SITE INTO AN OLIGONUCLEOTIDE TO INCREASE THE HCT OF THE OLIGONUCLEOTIDE AND IMPROVE PRIMING SPECIFICITY

It is shown in Example 3 that the introduction of an abasic site or mismatched site into an oligonucleotide primer will decrease the T_d and HCT of the respective derived primer compared to a perfected based pair "sister" primer. Abasic sites in polynucleotides of oligonucleotides can be introduced by the chemical or 20 enzymatic hydrolysis of the glycosidic bond. The resulting structure is apurinic or apyrimidinic which lacks the coding information and fails to base pair. The CE phosphoramidite of the tetrahydroduran derivative is commercially available (dSPACER, Glenn Research, Sterling, Virginia) as well as other spacer phosphoramidites (Glenn Research, Sterling, Virginia).

25

Effect of abasic substitution on the HCT of a set of oligonucleotides is shown in the Table below.

Table 12

Buffer Type	Oligo Type	HCT*	T _d *	Stringency Factor
1X PCR buffer	normal	18		
1X PCR buffer	abasic (dSPACER)	12		
1X PCR buffer	abasic (C3 spacer)	12		
0.5 M TMATCA	normal	14		
0.5 M TMATCA	abasic (dSPACER)	8		
0.5 M TMATCA	abasic (C3 spacer)	8		
2.0 M LiTCA	normal	12.5	44.5	4.97
2.0 M LiTCA	abasic (dSPACER)	10	39	6.37
2.0 M LiTCA	abasic (C3 spacer)	10	39	6.25
3.0 M GuSCN	normal	16	35.5	3.85
3.0 M GuSCN	abasic (dSPACER)	12.5	32	5.24
3.0 M GuSCN	abasic (C3 spacer)	12.5	31	5.31
* = °C				

The oligonucleotide is a 24-mer with the following sequence: 5'-hexylamine-TGTGGATCAGCA-spacer-GCAGGGAGTATG-3' where the spacer is either the C3-spacer or dSPACER from Glenn Research (Sterling, VA).

EXAMPLE 7

DETECTION OF A SINGLE BASE-PAIR MISMATCH ON A SOLID PHASE USING ABASIC SUBSTITUTED OLIGONUCLEOTIDES

This example describes the hybridization of an oligonucleotide containing an abasic site to an immobilized oligonucleotide using fluorescent tags. The set of probe oligonucleotides consists of one probe which forms perfect base-pairing and one oligonucleotide which contains the an abasic site when hybridized. The two oligonucleotides are labeled with different fluorochromes, and after hybridization at the T_d of the mismatch, the ratio of hybridized fluorochromes is determined.

A "target" oligonucleotide (DM0501: 5'-TTGATTCCCAATTATGCGAAGGAG-3') was immobilized on a set of solid

supports. ODN-beads (3/32nd inch diameter) were prepared as previously described (Van Ness et al., *Nuc. Acids Res.* 19:3345, 1991). The ODN-beads contained 0.01 to 1.2 mg/ bead of covalently immobilized ODN. DMO578 is the complement to DMO501 (perfect complement). DMO1969 is the complement to DMO501 with an abasic site at position 11. DMO1971 is the complement to DMO501 with an abasic site at position 12. Each probe oligonucleotide is labeled with either BODIPY, TAMRA or Texas Red. Hybridization reactions were assembled in 3 M GuSCN, 0.01 M Tris pH 7.6, 5 mM EDTA at 50 ng/ml respective probe. Equal molar ratios of each probe type were used in each hybridization in the presence of 3 solid supports per tube.

Hybridizations were at 42°C for 30 minutes with constant agitation. The beads were washed twice with 3 M GuSCN at 42°C and then with SDS/FW 5 times.

To denature the probe oligonucleotide, the solid supports were placed in 200 µl TE (TE is 0.01 M Tris, pH 7.0, 5 mM EDTA). The mixture is incubated for 10 minutes at 100°C. Fluorescence is measured in a black microtiter plate. The solution is removed from the incubation tubes (200 microliters) and placed in a black microtiter plate (Dynatek Laboratories, Chantilly, VA). The plates are then read directly using a Fluoroskan II fluorometer (Flow Laboratories, McLean, VA) using an excitation wavelength of 495 nm and monitoring emission at 520 nm for fluorescein, using an excitation wavelength of 591 nm and monitoring emission at 612 nm for Texas Red. and using an excitation wavelength of 570 nm and monitoring emission at 590 nm for lissamine or TAMRA.

The results are as follows:

Table 13

Probe Mix	Fluorochrome ratio in hybridization mix	Fluorochrome ratio after denaturing
578TR/578BD	2.1/1	2.1/1
578TR/1969BD	1.8/1	25/1
578TR/1971TA	0.024/1	0.6/1
578BD/1971TA	0.015/1	0.36/1

The results indicate that there is no effect of the fluorochrome on the hybridization as indicated in line 1 that Texas Red (TR) 578 oligonucleotide and 578-BD (BODIPY) competed evenly for hybridization to the immobilized target since the ratio of labels did not change after hybridization. There is an average of a 20-fold

enrichment of perfectly based probes over the abasic modified in GuSCN; allowing much higher levels of discrimination in hybridization reactions.

EXAMPLE 8

5 EFFECTS OF INTRODUCING A DEOXYNEBULARINE RESIDUE INTO AN OLIGONUCLEOTIDE PRIMER USED IN AMPLIFICATION

10 This example describes the use of oligonucleotide primers substituted with either abasic or deoxyNebularine residues to increase the specificity of priming in amplification reactions.

The primers used in this experiment are described by Rychlik (Rychlik, *Biotechniques*, 18:84-90, 1995). Primers may be synthesized or obtained as gel-filtration grade primers from Midland Certified Reagent Company (Midland Texas).

15 Amplification reactions are either *Taq* DNA polymerase-based (10 mM Tris-HCl pH 8.3, 1.5 mM MgCl₂, 50 mM KCl), or *Pfu* DNA polymerase based (20 mM Tris-HCl pH 8.75, 2.0 mM MgCl₂, 10 mM KCl, 10 mM (NH₄)₂SO₄, 0.1% Triton X-100, 0.1 mg/ml bovine serum albumin (BSA)). The total deoxynucleoside triphosphate (dNTPs) concentration in the reactions is 0.8 mM, the primer concentration is 200 nM (unless otherwise stated) and the template amount is 0.25 ng of bacteriophage lambda DNA per 25 μ l reaction. The amplification cycles consist of a denaturation step at 94°C for 5 minutes followed by 30 cycles of: 94°C for 45 seconds, 52°C for 45 seconds, at 20 72°C for 30 seconds, followed by a single step of 72°C for 5 minutes. Amplified DNA fragments are electrophoresed along with DNA standards through a 2% agarose gel in 0.5 X TBE buffer (45 mM Tris-borate, pH 8.0, 0.1 mM EDTA) and visualized after 25 staining with ethidium bromide. DNA is quantitated by densitometry. Each experiment is performed twice.

30 Two regions in the bacteriophage lambda DNA sequence (GenBank Accession #J02459) are chosen as the priming sites for amplification. The 5' primer has a stable GC-rich 3' end; the 3' primer is chosen so that a 381 bp product will result from the amplification. The primers used in this example are as follows:

Forward (5') primers:

H17: 5'-GAACGAAAACCCCCCGC-3'

35 H14: 5'-CTTCGAAAACCCCCCGC-3'

H11: 5'-CTTGCTAAACCCCCCGC-3'
AB1: 5'-GAACGA(dS)AACCCC(dS)CGC-3'
AB2: 5'-GAACGA(dS)AACCC(dS)CCGC-3'
AB3: 5'-GAACGA(dS)AACCCCCCG(dS)C-3'
5 DN1: 5'-GAACGA(dS)AACCCC(dN)CGC-3'
DN2: 5'-GAACGA(dN)AACCC(dN)CCGC-3'
DN3: 5'-GAACGA(dN)AACCCCCCG(dN)C-3'
DN4: 5'-GAACG(dN)AAACCC(dN)CCGC-3'
DN5: 5'-GAACG(dN)AAACC(dN)CCCGC-3'
10 DN6: 5'-CTTCGAAAACCC(dN)CCGC-3'

Reverse (3') primer:

reverse: 5'-GATCGCCCCAAAACACATA-3'

15 (dS) represents "dSPACER" residue and (dN) represents deoxyNebularine residue.

The forward primers are designed with their 5' ends variably mismatched to the target DNA. The H17 primer is a perfect match to the intended target, whereas the primer H14 is complementary only for the 14 nucleotides at the 3' end (the 3 nucleotides at the 5' end are mismatched). All of the primer pairs are used in 20 separate amplification reactions, and the annealing temperature is varied from 25°C to 65°C. A set of typical results are presented in the following table. Similar results are obtained for both *Taq* and *Pfu* polymerases.

Table 14

Primer Name	Number mismatches @ position in primer	Substitutions	Temp. Range (°C) that amplifications observed
H17	none	none	25 ---> 65
H14	3 @ 5'	none	25 ---> 65
H11	6 @ 5	none	25 ---> 50
AB1	2, @ 7, 14	dSpacer	no amplification
AB2	2, @ 7, 13	dSpacer	no amplification
AB3	2, @ 7, 16	dSpacer	no amplification
DN1	2, @ 7, 14	dNeb.	25 ---> 35
DN2	2, @ 7, 13	dNeb.	25 ---> 35
DN3	2, @ 7, 16	dNeb.	25 ---> 30
DN4	2, @ 6, 13	dNeb.	25 ---> 35
DN5	2, @ 6, 12	dNeb.	25 ---> 35
DN6	2, 3 @ 5', 13	dNeb.	25 ---> 30

These results indicate that the dSpacer substitution prevents the *Taq* or *Pfu* DNA polymerase from "reading through" the abasic site. That is, when the polymerase encounters an abasic residue, chain extension is terminated. Therefore, the priming site is not conserved during the second strand synthesis, and amplification of the target nucleic acid is not achieved. However, the polymerases can read through deoxyNebularine residues present in the oligonucleotide primers. Most likely, but not verified, deoxythymidine is inserted as the complementary base to deoxyNebularine. 5 However, the temperature range over which amplification is achieved is reduced compared to the temperature range for amplification using the H17 primer (from 25°C - 65°C down to 25°C to approximately 35°C). It is therefore apparent that the deoxyNebularine substituted primers can substantially increase the specificity of the PCR reaction. Priming was improved which led to the amplification of a specific 10 amplicon. 15

In a second series of experiments, the primer pairs are used in separate amplification reactions utilizing an annealing temperature of 42°C. The results are presented in Figure 12. Similar results are obtained for both the *Taq* and *Pfu* polymerases. As expected, the H17, H14 and H11 primers all give rise to a 381 bp 20 amplicon, despite the 3 base mismatches at the 5' end for the H14 primer and the 6 base mismatches at the 5' end for the H11 primer. As above, no amplification is observed using the AB1 primer containing abasic residues. In contrast, the DN1, DN2, and DN3 primers all give rise to a 381-bp amplicon, although no amplification is observed using

the DN6 primer, probably due to the mismatch of 3 bases at the 5'-end of the primer and the deoxyNebularine substitution at the 3' end of the primer. Thus, deoxyNebularine substituted primer can greatly increase the specificity of priming in the polymerase chain reaction.

5

EXAMPLE 9

EFFECTS OF INTRODUCING A DEOXYNEBULARINE RESIDUE INTO AN OLIGONUCLEOTIDE ON THE HCT OF THE OLIGONUCLEOTIDE

10 In Example 3, the introduction of an abasic site or mismatched site into an oligonucleotide primer decreases the T_d and HCT of the modified primer as compared to a perfectly based pair "sister" primer. The effect of deoxyNebularine substitutions on the HCT is also investigated.

15 DeoxyNebularine modified oligonucleotides can be synthesized by standard methods utilizing phosphoramidites. The CE phosphoramidite of the tetrahydronuran derivative, as well as other spacer phosphoramidites are commercially available (deoxyNebularine, Glenn Research, Sterling, Virginia). The oligonucleotide for the following experiments is synthesized as a 24-mer having the following sequence: 5'-hexylamine-TGTGGATCAGCA(dN)GCAGGAGTATG-3'.

20 The effect of the deoxyNebularine (dN) substitution on the HCT of a set of oligonucleotides is shown in the Table below.

Table 15

Buffer Type	Oligo Type	ΔHCT^*	T_d^*	Stringency Factor
1X PCR buffer	normal	18		
1X PCR buffer	abasic	12		
1X PCR buffer	deoxyNebularine	12		
0.5 M TMATCA	normal	14		
0.5 M TMATCA	abasic	8		
0.5 M TMATCA	deoxyNebularine	8		
2.0 M LiTCA	normal	12	44	5.0
2.0 M LiTCA	abasic	10	39	6.3
2.0 M LiTCA	deoxyNebularine	10	39	6.3
3.0 M GuSCN	normal	16	35	3.9
3.0 M GuSCN	abasic	12.5	32	5.2

* = °C

The deoxynebularine substituted oligonucleotide showed the same decrease in the HCT as the abasic substituted oligonucleotide.

5

EXAMPLE 10

DETECTION OF A SINGLE BASE-PAIR MISMATCH ON A SOLID PHASE USING DEOXYNEBULARINE SUBSTITUTED OLIGONUCLEOTIDES

10 This example describes the hybridization of an oligonucleotide containing a deoxyNebularine site to an immobilized oligonucleotide (target). The set of probe oligonucleotides consists of one probe that is perfectly complementary to the target, and a second oligonucleotide that contains a deoxyNebularine site. The probe oligonucleotides are labeled with fluorescent tags to aid in detection of hybridization.

15 For this data, the two oligonucleotides are labeled with different fluorochromes, and after hybridization at the T_d of the mismatch, the ratio of hybridized fluorochromes is determined.

A target oligonucleotide, 5'-TTGATTCCCAATTATGCGAAGGAG-3' (DMO501), is immobilized on a solid support. Oligonucleotide containing beads

(ODN-beads) that are 3/32nd inch diameter are prepared as previously described (Van Ness et al., *Nuc. Acids Res.* 19:3345, 1991). The ODN-beads contain from 0.01 to 1.2 mg/bead of covalently immobilized ODN. Probe oligonucleotides include DMO578, which is the perfect complement to DMO501. DMO1969, which is the complement to DMO501 but has a deoxyNebularine residue at position 11, DMO1971, which is the complement to DMO501 but has a deoxyNebularine site at position 12. Each probe oligonucleotide is labeled with either BODIPY, TAMRA or Texas Red. Hybridization reactions contain 50 ng/ml of each probe in a solution comprising 3 M GuSCN, 0.01 M Tris pH 7.6, and 5 mM EDTA. Equal molar ratios of each probe are used for each hybridization to 3 solid supports contained in a tube. Hybridizations are carried out at 42°C for 30 minutes with constant agitation. The beads are washed twice with 3 M GuSCN at 42°C followed by five washes of SDS/FW.

To denature the probe/target duplexes, the solid supports are placed in 200 µl TE (0.01 M Tris, pH 7.0, 5 mM EDTA) and incubated for 10 minutes at 100°C. The solution (200 µl) is removed from the incubation tubes and placed in a black microtiter plate (Dynatek Laboratories, Chantilly, VA) for measurement of fluorescence. The plates are then read directly in a Fluoroskan II fluorometer (Flow Laboratories, McLean, VA) using an excitation wavelength of 495 nm and monitoring emission at 520 nm for fluorescein, using an excitation wavelength of 591 nm and monitoring emission at 612 nm for Texas Red, and using an excitation wavelength of 570 nm and monitoring emission at 590 nm for lissamine or TAMRA.

The results are presented in the following table:

Table 16

Probe Mix	Fluorochrome ratio in hybridization mix	Fluorochrome ratio after denaturing
578TR/578BD	5.6/1	5.6/1
578TR/1969BD	2.0/1	36/1
578TR/1971TA	0.018/1	0.7/1
578BD/1971TA	0.022/1	0.48/1

The results indicate an average of 20-fold enrichment of perfectly based probes over the deoxyNebularine modified probes in GuSCN; allowing much higher levels of discrimination in hybridization reactions. This enrichment is not due to the presence of the fluorochrome, as the fluorochrome has no measurable effect on the hybridization. As indicated in line 1, Texas Red (TR) 578 oligonucleotide and 578-BD

(BODIPY) competed equivalently for hybridization to the immobilized target as evidenced by the same ratio of labels before and after hybridization.

EXAMPLE 11

5 **DETECTION OF A SINGLE BASE-PAIR MISMATCH ON A SOLID PHASE**
 USING ABASIC SUBSTITUTED OLIGONUCLEOTIDES

This example describes the use of abasic substituted oligonucleotide probes to detect single base pair mismatches. As shown herein, an increase in 10 efficiency is observed in detecting single base-pair mismatches using abasic substituted oligonucleotide probes as compared to standard probes.

Target oligonucleotides are covalently attached to membrane filters (Magna Graph nylon membrane filters, Micron Separations, Westboro, MA) (Van Ness et al., *Nuc. Acids Res.* 19:3345, 1991). The target oligonucleotides are based on the 15 sequence: 5'-TGTGGATCAGCAAGCAGGAGTATC-3' and contain either a G→A, T→C, T→T, G→T, or T→G mismatch at positions 13 or 14 in the target oligonucleotides. After attachment of the oligonucleotides to the membrane, the sheet is blocked for 10 min with gentle mixing in a succinic anhydride solution (2.5 g of succinic anhydride dissolved in 25 ml m-pyrol mixed with 125 ml 0.1 M NaBorate pH 20 8.5). The sheets are then washed 5 times with a solution of 10 mM Tris, 5 mM EDTA (TE). The sheets are additionally blocked for 30 min with gentle mixing with a solution of 1% bovine serum albumin (Fraction 5, Sigma) and containing 100 µg/ml fragmented, single strand herring sperm DNA. The sheets were then washed 5 times in TE.

The following biotinylated probes
25 control probe: 5'-ACACCTAGTCGTTCGTCCTCATAC-3',
 8S abasic probe: 5'-ACACCT(dS)GTCGTTCGTCCTCATAC-3', and
 6S abasic probe: 5'-ACACCT(dS)GTCGTTCGTCCTC(DS)TAC-3'
 are added to the sheet at a final concentration of 10 ng/ml in 1 ml of 3 M GuSCN, and the sheets are incubated at 28°C for 30 minutes. The sheets are then rinsed 30 four times in 1xSSC/0.1% SDS for 1 minute each wash, followed by two rinses in Wash Solution (0.01 M Tris pH 7.2, 0.1 M NaCl, 0.005 M EDTA, 0.1% Tween 20).

The streptavidin/alkaline phosphatase conjugate (Vector, Burlingame, CA) is diluted 1:10,000 in wash solution. The sheets are then incubated in this solution for 1 hour at room temperature with shaking. The sheets are subsequently rinsed four 35 times with wash solution and once with detection buffer (0.1 M NaCl, 0.01 M Tris pH 8.5, 0.05 M MgCl₂) for 5 minutes. The alkaline phosphatase substrate is prepared by

dissolving a BCIP/NBT tablet (Schleicher and Schuell, part #78349, Keene, NH) in 30ml dH₂O. The reaction is carried out for 0.5 to 4 hours at room temperature. The sheets are then rinsed with water and dried. A text scanner is used to detect signal.

As shown in Figure 13, hybridization to the control probe is observed for 5 each target oligonucleotide, even for those that are mismatched. However, the 6S abasic-modified probe hybridized nearly exclusively to the perfect match target oligonucleotide. The 8S abasic-modified probe also hybridized preferentially to the perfect match target oligonucleotide. The density for each target is presented in the following table in relative intensity units:

10

Table 17

Oligo	None	G/A	C/T	T/T	G/T	T/G
Control	90	82	26	90	91	45
6S	52	0	0	0	10	3
8S	76	35	2	35	45	30

The following table presents the ratio of mismatch density to control density.

15

Table 18

Oligo	None	G/A	C/T	T/T	G/T	T/G
Control	1	0.91	0.28	1	1.01	0.5

20

EXAMPLE 12

HIGH THROUGHPUT ANALYSIS OF HELICAL COIL TRANSITIONS OF OLIGONUCLEOTIDES.

A capture oligonucleotide (36-mer) was covalently linked to nylon bead via a C6-amine tail as previously described (Van Ness et al., *Nuc. Acids Res.* 19:3345, 1991). Oligonucleotides (of various lengths as described in the text) were labeled via a 25 C6 amine spacer with Texas Red (fluorescein, lissamine or TAMRA can also be used)

and were hybridized to the capture oligonucleotide in a 1.5M guanidinium thiocyanate solution (other hybridization solutions as described in the text can also be used).

Specifically, the "signal" oligonucleotide was synthesized by Midland Certified Reagent Company (Midland, Texas) at 1 μ M scale. The oligo was diluted to 5 250 μ L in TE buffer which was used as a stock solution. The signal oligo was further diluted for hybridization by removing 25 μ L of the stock solution and mixing it into 975 μ L of 1.5M guanidinium thiocyanate solution (other hybridization solutions as described in the text can also be used). This working stock was aliquoted into a Cetus tube (100 μ L/tube). A nylon pin was immersed in the solution for 15 minutes at ambient 10 temperature to allow the signal oligo to hybridize to the immobilized capture oligo. The beads were then washed to remove unhybridized signal oligonucleotide 1x with 0.01 M Tris pH 7.0, 5 mM EDTA, and 0.1 M NaCl; 2x with 0.01 M Tris pH 7.0, 5 mM EDTA, 0.1 M NaCl, and 0.1% SDS; 1x with 0.01 M Tris pH 7.0, 5 mM EDTA, and 0.1 M NaCl (TEN: 0.01M Tris pH 7.5, 1mM EDTA, 100mM NaCl; TENS: 0.01M Tris pH 15 7.5, 1mM EDTA, 100mM NaCl, 0.1% SDS).

Test solutions were aliquoted into wells of a polycarbonate thermowell plate (Corning Costar Corp., Cambridge, MA) and the plate placed in an MJ thermal cycler (MJ Research Company, Watertown, MA). The beads were serially transferred between the wells of the plate; every 2.5 to 5 minutes the temperature increases by 5°C 20 starting at 10°C and reaching 85 to 100°C at the final point. After the melting process was completed, the liquid in the polycarbonate thermowell plates was transferred to a black 96 well microtiter plate (Dynatek Laboratories, Chantilly, VA). The plates were then read directly using a Fluoroskan II fluorometer (Flow Laboratories, McLean, VA) using an excitation wavelength of 495 nm and monitoring emission at 520 nm for 25 fluorescein, using an excitation wavelength of 591 nm and monitoring emission at 612 nm for Texas Red, and using an excitation wavelength of 570 nm and monitoring emission at 590 nm for lissamine or TAMRA. The level of fluorescence correlates with the amount of signal oligonucleotide that has melted from the capture oligo.

To calculate the T_d , cumulative counts eluted at each temperature were 30 plotted against temperature. The temperature at which 50% of the material dissociates from the bead is the T_d . The data was exported into a spreadsheet and melt curves were generated for each solution. From these melt curves, T_d , ΔHCT , and ΔT_d were calculated.

EXAMPLE 13

IDENTIFICATION OF HYBRIDIZATION SOLUTIONS WHICH EFFECTIVELY NEUTRALIZE THE G+C CONTENT OF NUCLEIC ACID DUPLEXES.

5 This example describes the identification and use of novel compounds that reduce or eliminate the effects of G+C content on the melting behaviour of nucleic acid duplexes. Also, as shown herein, an increase in efficiency is observed in detecting single base-pair mismatches using modified oligonucleotide probes as compared to standard probes.

10 Solutions and Reagents

Filter wash (FW) is 0.09 M NaCl, 540 mM Tris pH 7.6, 25 mM EDTA. SDS/FW is FW with 0.1% sodium dodecyl sulfate (SDS). Hybridization solutions contain the text specified concentration of hybotrope of G+C neutralizing compound, 0.1 to 2% N-lauroylsarcosine (sarcosyl), 50 mM Tris pH 7.6 (in some cases) and 0.5 to 15 25 mM EDTA. Formamide hybridization solution contains 30% formamide, 0.09 M NaCl, 40 mM Tris-HCl pH 7.6, 5 mM EDTA and 0.1% SDS. GuSCN is purchased from Kodak (Rochester, NY). GuCl, lithium hydroxide, trichloroacetic acid, NaSCN, NaClO₄ and KI, are purchased from Sigma (St. Louis, MO). CsTFA is purchased from Pharmacia (Piscataway, NJ). The amine based compounds were purchased from Sigma 20 (St. Louis, MO), Aldrich (Milwaukee, WI) or from Fluka (Ronkonkoma, NY)

Preparation of LiTCA, TMATCA and TEATCA and other Amine-based TCA, TFA and acetate salts.

LiTCA and TMATCA, and TEATCA are prepared by the dropwise titration of a 3 N solution of LiOH, TEAOH and TMAOH respectively, with 25 trichloroacetic acid (100% w/v, 6.1 N) to pH 7.0 on ice with constant stirring. The salt is evaporated to dryness under vacuum, washed once with ether and dried. The acetate, trichloroacetate, or trifluoroacetate salts of the amine containing compounds were synthesized by neutralizing the respective amines with acetic acid, trichloroacetic acid or with trifluoroacetate to pH 6.0 to pH 8.5, depending upon the application. The 30 resulting salt solution was then diluted to the concentration desired as stated in the figures or tables in this example. In some cases the salt was then dissolved in water to a final concentration of 0.1 to 3.0 M. The resulting salt solution was in some cases then buffered with Tris-HCl, pH 7.0-8.5, and detergents, such as sarkosyl, are added to about 0.1%, and optionally EDTA is added to 0.5 to 5 mM. The oligonucleotide that was

tethered to the bead was DMO-2060: 5'-hexylamine-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' (oligonucleotide immobilized on the nylon bead); abd the probe oligonucleotides were: DMO-2055: 5'-TEXAS RED- TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' (perfect complement); 5 DMO-2058; 5'-TEXAS RED- TGT/GGA/TCA/GGA/AGC/AGG/AGT/ATG-3' (mismatch complement); and DMO-2058-dN: 5'-TEXAS RED- TGT/GGA/TCA/G(deoxynebularine)A/AGC/AGG/AGT/ATG-3' (deoxynebularine mismatch complement).

As shown in Table 19 numerous amine-based hybridization solutions (in the 100 mM concentration range, 500 mM concentration range and 1000 mM concentration range) have been identified which give rise to a ΔT_d of 9 °C or less 5 between oligonucleotide duplexes of G+C content of 27% to 83%. Novel hybridization solutions were prepared which demonstrate properties not previously described for a hybridization solution.

These hybridization solutions possess the property of neutralizing the differences in G+C and A+T base-pairing strength. Some of the solutions (most 10 tripropylamine acetate, bis(2-methoxyethyl)amine trifluoroacetate, disopropylamine trifluoroacetate, n,n dimethylaminobutane trifluoroacetate at 100 mM; triethanolamine acetate, notably n,n dimethylcyclohexylamine trifluoroacetate, n,n dimethylheptylamine acetate at 500 mM; notably n,n dimethylcyclohexylamine trifluoroacetate, tripropylamine acetate, dibutylamine acetate, n,n dimethylheptylamine 15 acetate, dimethylhexylamine acetate, dicyclohexylamine acetate at 1000 mM) simultaneously lowers the T_d and ΔT_d . Others such as increase ΔT_d (1-ethylpiperidine acetate, etc.) In the table below the characteristics of the novel hybridization solutions and hybotropes are described. The following ΔT_d s as a function of G+C content were obtained from the melt curves described below: Novel hybridization solutions have 20 also been identified which neutralize the effects of G+C content on the melting behaviour of nucleic acid duplexes. These solutions are in some cases hybotropes and in other cases can be used as PCR buffers or as hybridization solutions which minimize the effects of G+C content on nucleic acid duplexes. These new hybridization solutions, their properties, and their preparation are described in Example 12. Figure 14 25 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The capture oligonucleotide is a 36-mer (DMO-GC36cap: 5'-hexylamine-GCA/GCC/TCG/CGG/AGG/CGG/ATG/ATC/GTC/ATT/AGT/ATT-3') and three complementary oligos which are labelled with the fluorochrome are DMO-

83GC: 5'-Texas Red- CCG/CCT/CCG/CGA/GGC/TGC-3'; DMO-50GC: 5'-Texas Red- AAT/GAC/GAT/CAT/CCG/CCT-3'; DMO-27GC: -Texas Red- AAT/ACT/AAT/GAC/GAT/CAT-3'. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis). The melting solution was 100 mM 2-methoxyethylamine trifluoroacetate. The maximum difference between the 3 melting curves in the T_d was 6 C. The helical coil transition of the 27% G+C content was 21 C, 50% G+C was 33 C and for the 83% G+C duplex was 29 C. Note that the helical coil transitions (HCTs) of the 3 different G+C content oligonucleotides is different. This is in contrast to the case with diisobutylamine as shown in Figure 15. Figure 15 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83% (the same system as described in Figure 14). The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis). The melting solution was 100 mM diisobutylamine acetate. The maximum difference between the 3 melting curves in the T_d was 5 C. The helical coil transition of the 27% G+C content was 22 C, 50% G+C was 26 C and for the 83% G+C duplex was 25 C. The helical coil transitions for the three oligonucleotide duplexes are very similar. This is the behaviour that is preferred for use in array hybridizations or polymerase chain reactions.

In Figure 16 the inability of GuSCN to neutralize G+C content is shown. Figure 16 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83% (the same capture and probe oligonucleotides as described in figure 14). The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis). The melting solution was 2 M Guanidinium thiocyanate. The maximum difference between the 3 melting curves in the T_d or T_m is 16 C. The helical coil transition of the 27% G+C content was 28 C, for the 50% G+C duplex was 30 C and for the 83% G+C duplex was 32 C. Similar results were obtained with 1x PCR buffer (figure 17) and 1x SSC buffer (Figure 18). There was also no neutralization of G+C content with 20% formamide (Figure 19). Figure 17 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83% (the same duplex system as described in Figure 14). The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature ($^{\circ}$ C; x-axis). The melting solution was 1x PCR buffer. The maximum difference between the 3 melting curves in the T_d was 14 C. The helical coil transition of the 27% G+C content was 17 C, for the 50% G+C duplex

was 22 C and for the 83% G+C duplex was 23 C. Figure 18 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis).

5 The melting solution was 1x SSC. The maximum difference between the 3 melting curves in the T_d is 13 C. The helical coil transition of the 27% G+C content was 20 C, for the 50% G+C duplex was 22 C and for the 83% G+C duplex was 23 C. Figure 19 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The temperature difference between any two T_d s at $\alpha = 0.5$ is

10 defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 20% formamide, 10 mM Tris pH 7.6, and 5 mM EDTA with 0.1 % sarkosyl. The maximum difference between the 3 melting curves in the T_d is 14 C. The helical coil transition of the 27% G+C content was 15 C, for the 50% G+C duplex was 16 C and for the 83% G+C duplex was 20 C.

15 In contrast to the situation in Figures 17, 18 and 19, Figure 20 shows the melting behaviour of the 3 different G+C oligonucleotide duplexes in 1 M dicyclohexylamine acetate. Figure 20 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand

20 DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 1 M dicyclohexylamine acetate. The maximum difference between the 3 melting curves in the T_d was 3 C. The helical coil transition of the 27% G+C content was 13 C, for the 50% G+C duplex was 17 C and for the 83% G+C duplex was 19 C. This is an ideal profile for a hybotrope. In contrast the the narrow helical coil transition observed in

25 Figure 20, a much wider HCT is observed with 500 mM n-ethylbutylamine acetate. Figure 21 is a graph showing the difference in T_d between three duplexes, that vary in G+C content from 27% to 83%. The capture oligonucleotide is a 36-mer (DMO-GC36cap: 5'- hexylamine-GCA/GCC/TCG/CGG/AGG/CGG/ATG/ATC/GTC/ATT/AGT/ATT-3') and three complementary oligos which are labelled with the

30 fluorochrome are DMO-83GC: 5'-Texas Red- CCG/CCT/CCG/CGA/GGC/TGC-3'; DMO-50GC: 5'-Texas Red- AAT/GAC/GAT/CAT/CCG/CCT-3'; DMO-27GC: -Texas Red-AAT/ACT/AAT/GAC/GAT/CAT-3'. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 500 mM n-ethylbutylamine acetate. The maximum difference between the 3 melting curves in the

35

T_d was 1 C. The helical coil transition of the 27% G+C content was 22 C, for the 50% G+C duplex was 22 C and for the 83% G+C duplex was 26 C.

The ability of some of the G+C neutralizing buffer to act as hydrotropes is illustrated in Figure 22. Figure 22 is a graph showing the difference in T_d between 5 three duplexes, one that is perfectly based-paired and the other two that contains a mismatch or a deoxynebularine substitution. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). DMO-2060: 5'-hexylamine-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' (oligonucleotide 10 immobilized on the nylon bead.); DMO-2055: 5'-TEXAS RED-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' (perfect complement); DMO-2058: 5'-TEXAS RED- TGT/GGA/TCA/GGA/AGC/AGG/AGT/ATG-3' (mismatch complement); and DMO-2058-dN: 5'-TEXAS RED-TGT/GGA/TCA/G(deoxynebularine)A/AGC/AGG/AGT/ATG-3' (deoxynebularine 15 mismatch complement). The melting solution was 1 M diisopropylamine acetate. The maximum difference between the 3 melting curves in the T_d was 6 C. The helical coil transition (HCT) of the true mismatch was 14 C; the HCT for the deoxynebularine mismatch duplex was 14 C and the HCT for the perfectly based paired duplex was 16 C.

20 The same situation was observed for 1 M diisopropylamine acetate (Figure 22), 1 M n,n-dimethylcyclohexylamine acetate (Figure 23) and 1 M dicyclohexylamine acetate (Figure 24) and n,n-dimethylhexylamine acetate (Figure 25). Figure 23 is a graph showing the difference in T_d between three duplexes, one that is perfectly based-paired and the other two that contains a mismatch or a deoxynebularine 25 substitution. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). DMO-2060: 5'-hexylamine-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' (oligonucleotide immobilized on the nylon bead.); DMO-2055: 5'-TEXAS RED-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' (perfect complement); DMO-2058: 30 5'-TEXAS RED- TGT/GGA/TCA/GGA/AGC/AGG/AGT/ATG-3' (mismatch complement); and DMO-2058-dN: 5'-TEXAS RED-TGT/GGA/TCA/G(deoxynebularine)A/AGC/AGG/AGT/ATG-3' (deoxynebularine mismatch complement). The melting solution was 1 M n,n-dicyclohexylamine acetate. 35 The maximum difference between the 3 melting curves in the T_d or T_m is 4 C. The helical coil transition (HCT) of the true mismatch was 15 C; the HCT for the

deoxynebularine mismatch duplex was 15 C and the HCT for the perfectly based paired duplex was 15 C.

Figure 24 is a graph showing the difference in T_d between three duplexes, one that is perfectly based-paired and the other two that contains a mismatch or a deoxynebularine substitution. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). DMO-2060: 5'-hexylamine-GTC/ATA/CTC/CTG/CTT/GCT/GAT/CCA/CAT/CTG-3' (oligonucleotide immobilized on the nylon bead.); DMO-2055: 5'-TEXAS RED-TGT/GGA/TCA/GCA/AGC/AGG/AGT/ATG-3' (perfect complement); DMO-2058; 5'-TEXAS RED-TGT/GGA/TCA/GGA/AGC/AGG/AGT/ATG-3' (mismatch complement); and DMO-2058-dN: 5'-TEXAS RED-TGT/GGA/TCA/G(deoxynebularine)A/AGC/AGG/AGT/ATG-3' (deoxynebularine mismatch complement). The melting solution was 1 M n,n-dicyclohexylamine acetate. The maximum difference between the 3 melting curves in the T_d is 4 C. The helical coil transition (HCT) of the true mismatch was 17 C; the HCT for the deoxynebularine mismatch duplex was 17 C and the HCT for the perfectly based paired duplex was 15 C.

Figure 25 is a graph showing the difference in T_d between three duplexes, one that is perfectly based-paired and the other two that contains a mismatch or a deoxynebularine substitution. The temperature difference between any two T_d s at $\alpha = 0.5$ is defined as the ΔT_d . The percentage of single strand DNA (y-axis) is plotted versus temperature (°C; x-axis). The melting solution was 100 mM n,n-dimethylhexylamine acetate. The maximum difference between the 3 melting curves in the T_d is 9 C. The helical coil transition (HCT) of the true mismatch was 15 C; the HCT for the deoxynebularine mismatch duplex was 15 C and the HCT for the perfectly based paired duplex was 15 C.

It will be appreciated that, although specific embodiments of the invention have been described herein for purposes of illustration, various modifications may be made without departing from the spirit and scope of the invention. Accordingly, the invention is not limited except as by the appended claims.

CLAIMS

We claim:

1. A composition comprising a nucleic acid and a salt, the salt comprising an anion and a cation, the anion selected from halogenated acetate, propionate and halogenated propionate, the cation selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.
2. The composition of claim 1 wherein the anion is trichloroacetate.
3. The composition of claim 1 wherein the anion is trifluoroacetate.
4. The composition of claim 1 wherein the cation is formed from atoms selected from 2-20 carbon atoms, 0-5 oxygen atoms and 1-5 nitrogen atoms.
5. The composition of claim 1 wherein the cation has the structure $N(R)_4$, wherein R is a C_1 - C_{12} hydrocarbyl and any two R groups may join together to form a cyclic structure with the nitrogen atom.
6. The composition of claim 5 wherein R is independently selected from the group consisting of C_1 - C_{12} alkyl, C_3 - C_{12} cycloalkyl and C_7 - C_{12} arylalkyl.
7. The composition of claim 1 wherein the cation has the structure $HN(R)_3$, wherein R is a C_1 - C_{12} hydrocarbyl and any two R groups may join together to form a cyclic structure with the nitrogen atom.
8. The composition of claim 7 wherein R is independently selected from the group consisting of C_1 - C_{12} alkyl, C_3 - C_{12} cycloalkyl and C_7 - C_{12} arylalkyl.
9. The composition of claim 1 wherein the cation has the structure $N(H)_2(R)_2$ wherein R is a C_1 - C_{12} hydrocarbyl and the two R groups may join together to form a cyclic structure with the nitrogen atom.
10. The composition of claim 9 wherein R is independently selected from the group consisting of C_1 - C_{12} alkyl, C_3 - C_{12} cycloalkyl and C_7 - C_{12} arylalkyl.

11. The composition of claim 1 wherein the cation is selected from the group consisting of ethylbutylammonium, 1-methylimidazole, 1-methylpiperidine, 1-methylpyrrolidine, 3-methoxypropylamine, triethylamine, bis(2-methoxyethyl)amine, diallylamine, dibutylamine, diisobutylamine, N,N-dimethylaminobutane, N,N-dimethylcyclohexylamine, N,N-dimethylheptylamine, N,N-dimethylhexylamine, triethanolamine, 1-ethylpiperidine, dicyclohexylamine, diisopropylamine, dipropylamine, N,N-dimethylisopropylamine, N-ethylbutylamine, tetraethylammonium, tripropylamine, 2-methoxyethylamine, and N,N-dimethyloctylamine, and the anion is selected from the group consisting of trichloroacetate and trifluoroacetate.
12. The composition of claim 1 wherein the nucleic acid comprises a chain of 6-100 nucleotides.
13. The composition of claim 1 wherein the nucleic acid is DNA.
14. The composition of claim 1 wherein the nucleic acid is immobilized on a solid support.
15. The composition of claim 1 wherein the nucleic acid forms an array on a solid support.
16. The composition of any of claims 1-15 or 17-43 further comprising an enzyme selected from polymerase and ligase.
17. The composition of claim 1 further comprising water.
18. The composition of claim 17 wherein the salt is completely dissolved in the water at a concentration of from 50mM to 6M at room temperature.
19. The composition of claim 17 wherein the nucleic acid is present at a concentration of from 10^{-6} to 10^{-18} g/mL.
20. The composition of claim 17 further comprising at least one of a buffer, detergent and chelator.

21. A composition which is non-flowing comprising a oligonucleotide of 6-100 nucleotides and a salt, the salt comprising an anion and a cation, the anion selected from acetate, halogenated acetate, propionate, and halogenated propionate, the cation selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

22. A composition which is free from organic solvent, comprising a oligonucleotide of 6-100 nucleotides and a salt, the salt comprising an anion and a cation, the anion selected from acetate, halogenated acetate, propionate, and halogenated propionate, the cation selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

23. The composition of any of claims 21 or 22 wherein the anion is acetate.

24. The composition of claim 21 wherein the cation is formed from atoms selected from 2-20 carbon atoms, 0-5 oxygen atoms and 1-5 nitrogen atoms.

25. The composition of claim 21 wherein the cation has the structure $N(R)_n$, wherein R is a C_1 - C_{12} hydrocarbyl and any two R groups may join together to form a cyclic structure with the nitrogen atom.

26. The composition of claim 21 wherein the cation has the structure $HN(R)_n$, wherein R is a C_1 - C_{12} hydrocarbyl and any two R groups may join together to form a cyclic structure with the nitrogen atom.

27. The composition of claim 21 wherein the cation has the structure $N(H)_2(R)_2$ wherein R is a C_1 - C_{12} hydrocarbyl and the two R groups may join together to form a cyclic structure with the nitrogen atom.

28. The composition of claim 21 wherein the nucleic acid is DNA.

29. The composition of claim 21 wherein the nucleic acid forms an array on a solid support.

30. The composition of claim 21 further comprising water.

31. The composition of claim 30 wherein the salt is completely dissolved in the water at a concentration of from 50mM to 6M at room temperature.

32. A composition comprising a nucleic acid and a salt, the nucleic acid immobilized on a solid support, the salt comprising an anion and a cation, the anion selected from acetate, halogenated acetate, propionate and halogenated propionate, the cation selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

33. The composition of claim 32 wherein the anion is selected from acetate, trifluoroacetate and trichloroacetate.

34. The composition of claim 32 wherein the cation is formed from atoms selected from 2-20 carbon atoms, 0-5 oxygen atoms and 1-5 nitrogen atoms.

35. The composition of claim 32 wherein the cation has the structure $N(R)_4$, wherein R is a C_1-C_{12} hydrocarbyl and any two R groups may join together to form a cyclic structure with the nitrogen atom.

36. The composition of claim 32 wherein the cation has the structure $HN(R)_3$, wherein R is a C_1-C_{12} hydrocarbyl and any two R groups may join together to form a cyclic structure with the nitrogen atom.

37. The composition of claim 32 wherein the cation has the structure $N(H)_2(R)_2$, wherein R is a C_1-C_{12} hydrocarbyl and the two R groups may join together to form a cyclic structure with the nitrogen atom.

38. The composition of claim 32 wherein the cation is selected from the group consisting of ethylbutylammonium, 1-methylimidazole, 1-methylpiperidine, 1-methylpyrrolidine, 3-methoxypropylamine, triethylamine, bis(2-methoxyethyl)amine, diallylamine, dibutylamine, diisobutylamine, N,N-dimethylaminobutane, N,N-dimethylcyclohexylamine, N,N-dimethylheptylamine, N,N-dimethylhexylamine, triethanolamine, 1-ethylpiperidine, dicyclohexylamine, diisopropylamine, dipropylamine, N,N-dimethylisopropylamine, N-ethylbutylamine, tetraethylammonium, tripropylamine, 2-methoxyethylamine, and N,N-dimethyloctylamine, and the anion is selected from the group consisting of trichloroacetate and trifluoroacetate.

39. The composition of claim 32 wherein the solid support is selected from materials having a planar surface and comprising quartz, gold, nylon-6,6, nylon, polystyrene, glass, and silicon.

40. The composition of claim 39 wherein the solid support is selected from a glass plate and a silicon wafer.

41. The composition of claim 32 wherein the nucleic acids are present in separated domains in an array of separated domains, where the number of domains present in an array is selected from the ranges 10 to 50, 50 to 400, and 400 to 800.

42. The composition of claim 41 wherein the domains substantially circular, where the circles have an average diameter of about 10 microns to 200 microns.

43. The composition of claim 32 comprising a plurality of nucleic acid sequences.

44. A salt selected from the group consisting of:

(a) an acetate salt of a cation of the formula $\text{HN}(\text{CH}_3)_2\text{R}_a$ wherein R_a is a $\text{C}_4\text{-C}_7\text{hydrocarbyl}$;

(b) a halogenated acetate salt of a cation of the formula $\text{HN}(\text{CH}_3)_2\text{R}_b$ wherein R_b is a $\text{C}_7\text{-C}_{12}\text{hydrocarbyl}$

(c) acetate and halogenated acetate salts of a cation of the formula $\text{H}_2\text{N}(\text{C}_5\text{-C}_7\text{cycloalkyl})\text{R}_c$ where R_c is a $\text{C}_1\text{-C}_{12}\text{hydrocarbyl}$;

(d) acetate and halogenated acetate salts of N-substituted piperidine, wherein the nitrogen atom of piperidine is substituted with $\text{C}_1\text{-C}_{12}\text{hydrocarbyl}$.

45. The salt of claim 44 wherein hydrocarbyl is selected from alkyl, alkenyl, alkynyl, cycloalkyl, cycloalkenyl, aryl, aralkyl, and alkylaryl.

46. An oligonucleotide in solution comprising a plurality of fragments, each fragment shown schematically by structure (1)

wherein,

B_1, B_2, B_3 represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

— represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B_3 and B_5 ;

the specificity spacer having steric and chemical properties such that

(a) it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

(b) it cannot enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2).

47. The oligonucleotide of claim 46 wherein the specificity spacer has the formula

wherein

Y is selected from oxygen, sulfur, methyl and amino when X is oxygen, or Y is selected from oxygen and sulfur when X is sulfur; and

SSC represents a specificity spacer component having a chain of 2-5 carbon atoms shown in the formula

wherein n is 0, 1, 2 or 3, and each of the shown 2-5 carbon atoms of the specificity spacer component may be independently substituted with C_1-C_{10} hydrocarbyl or C_1-C_{10}

C₁₀hydrocarbyloxy, and any two of the shown 2-5 carbon atoms which are bonded directly to one another may form a carbocyclic or heterocyclic 5-6 membered ring.

48. The oligonucleotide of claim 47 wherein n of the specificity spacer component is 1, and the specificity spacer component has the formula (2)

wherein n is 1 and X is selected from carbon, oxygen and sulfur, such that any carbon shown in formula (2), including X when it is carbon, may be substituted with hydrogen, C₁-C₁₀hydrocarbyl, C₁-C₁₀hydrocarbyloxy, a non-hydrogen bonding purine base analog or a non-hydrogen bonding pyrimidine base.

49. The oligonucleotide of claim 47 wherein the specificity spacer component has the formula (3)

wherein each of the three shown carbon atoms may be substituted with hydrogen, C₁-C₁₀hydrocarbyl or C₁-C₁₀hydrocarbyloxy.

50. The oligonucleotide of claim 47 wherein having a plurality of specificity spacers, where no two specificity spacers are adjacent to one another, all nearest specificity spacers are separated by 4-14 wild-type nucleotides, and specificity spacers constitute 15-60% of the positions occupied by specificity spacers and wild-type nucleotides.

51. The oligonucleotide of claim 50 wherein all nearest specificity spacers are separated by 5-6 wild-type nucleotides.

52. The oligonucleotide of claim 50 wherein all nearest specificity spacers are separated by 8-12 wild-type nucleotides.

53. An array comprising a plurality of oligonucleotides immobilized in an array format to a solid support, each oligonucleotide of the plurality comprising a plurality of fragments, each fragment shown schematically by structure (1)

wherein,

B_1, B_2, B_3 represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

— represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B_3 and B_5 ;

the specificity spacer having steric and chemical properties such that

(a) it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

(b) it cannot enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2).

54. The array of claim 53 wherein the specificity spacer has the formula

wherein

Y is selected from oxygen, sulfur, methyl and amino when X is oxygen, or Y is selected from oxygen and sulfur when X is sulfur; and

SSC represents a specificity spacer component having a chain of 2-5 carbon atoms shown in the formula

wherein n is 0, 1, 2 or 3, and each of the shown 2-5 carbon atoms of the specificity spacer component may be independently substituted with C₁-C₁₀hydrocarbyl or C₁-C₁₀hydrocarbyloxy, and any two of the shown 2-5 carbon atoms which are bonded directly to one another may form a carbocyclic or heterocyclic 5-6 membered ring.

55. The array of claim 53 wherein n of the specificity spacer component is 1, and the specificity spacer component has the formula (2)

wherein n is 1 and X is selected from carbon, oxygen and sulfur, such that any carbon shown in formula (2), including X when it is carbon, may be substituted with hydrogen, C₁-C₅hydrocarbyl, C₁-C₅hydrocarbyloxy, a non-hydrogen bonding purine base analog or non-hydrogen bonding pyrimidine base analog.

56. The array of claim 53 wherein the specificity spacer component has the formula (3)

wherein each of the three shown carbon atoms may be substituted with hydrogen, C₁-C₁₀hydrocarbyl or C₁-C₁₀hydrocarbyloxy.

57. The array of claim 53 wherein each of the plurality of oligonucleotides have a plurality of specificity spacers, where no two specificity spacers are adjacent to one another, all nearest specificity spacers are separated by 4-14 wild-type nucleotides, and specificity spacers constitute 15-60% of the positions occupied by specificity spacers and wild-type nucleotides.

58. The oligonucleotide of claim 53 wherein all nearest specificity spacers are separated by 5-6 wild-type nucleotides.

59. The oligonucleotide of claim 53 wherein all nearest specificity spacers are separated by 8-12 wild-type nucleotides.

60. An oligonucleotide in solution comprising a plurality of fragments, each fragment shown schematically by structure (1)

wherein,

B1, B2, B3 represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

— represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B_3 and B_5 ;

the specificity spacer having steric and chemical properties such that

(a) it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

(b) it enters into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2);

(c) it does not hydrogen-bond through any of adenine, guanine, cytosine, thymine or uracil.

61. The oligonucleotide of claim 60 wherein the specificity spacer has the formula

wherein

Y is selected from oxygen, sulfur, methyl and amino when X is oxygen, or Y is selected from oxygen and sulfur when X is sulfur; and

SSC represents a specificity spacer component having a chain of 2-5 carbon atoms shown in the formula

wherein n is 0, 1, 2 or 3, and each of the shown 2-5 carbon atoms of the specificity spacer component may be independently substituted with C₁-C₁₀hydrocarbyl or C₁-C₁₀hydrocarbyloxy, and any two of the shown 2-5 carbon atoms which are bonded directly to one another may form a carbocyclic or heterocyclic 5-6 membered ring.

62. The oligonucleotide of claim 61 wherein n of the specificity spacer component is 1, and the specificity spacer component has the formula (2)

wherein n is 1 and X is selected from carbon, oxygen and sulfur, such that any carbon shown in formula (2), including X when it is carbon, may be substituted with hydrogen, C₁-C₅hydrocarbyl, C₁-C₅hydrocarbyloxy, a purine base analog or a pyrimidine base analog, where the purine base analog and the pyrimidine base analog may hydrogen bond to a complementary strand..

63. The oligonucleotide of claim 61 wherein the specificity spacer component has the formula (3)

wherein each of the three shown carbon atoms may be substituted with hydrogen, C₁-C₁₀hydrocarbyl or C₁-C₁₀hydrocarbyloxy.

64. The oligonucleotide of claim 60 wherein having a plurality of specificity spacers, where no two specificity spacers are adjacent to one another, all nearest specificity spacers are separated by 4-14 wild-type nucleotides, and specificity spacers constitute 15-60% of the positions occupied by specificity spacers and wild-type nucleotides.

65. The oligonucleotide of claim 64 wherein all nearest specificity spacers are separated by 5-6 wild-type nucleotides.

66. The oligonucleotide of claim 64 wherein all nearest specificity spacers are separated by 8-12 wild-type nucleotides.

67. An array comprising a plurality of oligonucleotides immobilized in an array format to a solid support, each oligonucleotide of the plurality comprising a plurality of fragments, each fragment shown schematically by structure (1)

wherein,

B_1, B_2, B_3 represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

— represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B_3 and B_5 ;

the specificity spacer having steric and chemical properties such that

(a) it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

, and

(b) it enters into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2);

(c) it does not hydrogen-bond through any of adenine, guanine, cytosine, thymine or uracil.

68. The array of claim 67 wherein the specificity spacer has the formula

wherein

Y is selected from oxygen, sulfur, methyl and amino when X is oxygen, or Y is selected from oxygen and sulfur when X is sulfur; and

SSC represents a specificity spacer component having a chain of 2-5 carbon atoms shown in the formula

wherein n is 0, 1, 2 or 3, and each of the shown 2-5 carbon atoms of the specificity spacer component may be independently substituted with C₁-C₁₀hydrocarbyl or C₁-C₁₀hydrocarbyloxy, and any two of the shown 2-5 carbon atoms which are bonded directly to one another may form a carbocyclic or heterocyclic 5-6 membered ring.

69. The array of claim 68 wherein n of the specificity spacer component is 1, and the specificity spacer component has the formula (2)

wherein n is 1 and X is selected from carbon, oxygen and sulfur, such that any carbon shown in formula (2), including X when it is carbon, may be substituted with hydrogen, C₁-C₅hydrocarbyl, C₁-C₅hydrocarbyloxy, a purine base, a pyrimidine base, a non-hydrogen bonding purine base analog or a non-hydrogen bonding pyrimidine base.

70. The array of claim 68 wherein the specificity spacer component has the formula (3)

wherein each of the three shown carbon atoms may be substituted with hydrogen, C₁-C₁₀hydrocarbyl or C₁-C₁₀hydrocarbyloxy.

71. The array of claim 67 wherein each of the plurality of oligonucleotides have a plurality of specificity spacers, where no two specificity spacers are adjacent to one another, all nearest specificity spacers are separated by 4-14 wild-type nucleotides, and specificity spacers constitute 15-60% of the positions occupied by specificity spacers and wild-type nucleotides.

72. The oligonucleotide of claim 71 wherein all nearest specificity spacers are separated by 5-6 wild-type nucleotides.

73. The oligonucleotide of claim 71 wherein all nearest specificity spacers are separated by 8-12 wild-type nucleotides.

74. A composition comprising an oligonucleotide and a salt in solution, the oligonucleotide comprising a plurality of fragments, each fragment shown schematically by structure (1)

wherein,

represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B₃ and B₅;

the specificity spacer having steric and chemical properties such that

(a) it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

at least one of (b) and (c) where

(b) the specificity spacer cannot enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2);

(c) the specificity spacer can enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary sequence of structure (2) but the specificity spacer does not provide any base selected from adenine, guanine, thymine, uracil or cytosine for the hydrogen bonding;

and the salt is a hybotropic, where a hybotropic is any chemical or any mixture of a chemical in an aqueous or organic environment with buffers, chelators, salts and/or detergents that changes the enthalpy of a nucleic acid duplex by at least 20% when referenced to a standard salt solution (0.165 M NaCl, 0.01 M Tris pH 7.2, 5 mM EDTA and 0.1% SDS).

75. An array composition comprising a plurality of oligonucleotides immobilized in an array format to a solid support, each oligonucleotide of the plurality comprising a plurality of fragments, each fragment shown schematically by structure (1)

wherein,

represents a sequence of at least three nucleotides as found in wild-type DNA, where "B" represents a base independently selected at each location;

— represents a series of covalent chemical bonds termed a "specificity spacer," which separates and connects two bases B₃ and B₅;

the specificity spacer having steric and chemical properties such that

(a) it does not prevent hybridization between a fragment of structure (1) and an oligonucleotide fragment having a complementary base sequence, as shown schematically as structure (2)

at least one of (b) and (c) where

(b) the specificity spacer cannot enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary base sequence of structure (2);

(c) the specificity spacer can enter into hydrogen bonding with a base positioned opposite itself in a hybridized complementary sequence of structure (2) but the specificity spacer does not provide any base selected from adenine, guanine, thymine, uracil or cytosine for the hydrogen bonding;

the nucleic acid of formula (1) being in contact with a hybotrope, where a hybotrope is any chemical or any mixture of a chemical in an aqueous or organic environment with buffers, chelators, salts and/or detergents that changes the enthalpy of a nucleic acid duplex by at least 20% when referenced to a standard salt solution (0.165 M NaCl, 0.01 M Tris pH 7.2, 5 mM EDTA and 0.1% SDS).

76. The composition of any of claims 74 or 75 the specificity spacer has the formula

wherein

Y is selected from oxygen, sulfur, methyl and amino when X is oxygen, or Y is selected from oxygen and sulfur when X is sulfur; and

SSC represents a specificity spacer component comprising a chain of 2-5 carbon atoms shown in the formula

wherein n is 0, 1, 2 or 3, and each of the shown 2-5 carbon atoms of the specificity spacer component may be independently substituted.

77. The composition of claim 76 wherein the specificity spacer component has the formula (2)

wherein n is 1 and X is selected from carbon, oxygen and sulfur, such that any carbon shown in formula (2), including X when it is carbon, may be substituted with hydrogen, C₁-C₁₀hydrocarbyl, C₁-C₁₀hydrocarbyloxy, a non-hydrogen bonding purine base analog or a non-hydrogen bonding pyrimidine base.

78. The composition of claim 76 wherein the specificity spacer component has the formula (3)

wherein each of the three shown carbon atoms may be substituted with hydrogen, C₁-C₁₀hydrocarbyl or C₁-C₁₀hydrocarbyloxy.

79. The composition of any of claims 74 or 75 wherein the oligonucleotides have a plurality of specificity spacers, where no two specificity spacers are adjacent to one another, all nearest specificity spacers are separated by 4-14 wild-type nucleotides, and specificity spacers constitute 15-60% of the positions occupied by specificity spacers and wild-type nucleotides.

80. The composition of claim 79 wherein all nearest specificity spacers are separated by 5-6 wild-type nucleotides.

81. The composition of claim 79 wherein all nearest specificity spacers are separated by 8-12 wild-type nucleotides.

82. The composition of any of claims 74 or 75 wherein the salt comprises an anion and a cation, the anion selected from acetate, halogenated acetate, propionate and halogenated propionate, the cation selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

83. The composition of claim 82 wherein the anion is trichloroacetate.
84. The composition of claim 82 wherein the anion is trifluoroacetate.
85. The composition of claim 82 wherein the cation is formed from atoms selected from 2-20 carbon atoms, 0-5 oxygen atoms and 1-5 nitrogen atoms.
86. The composition of claim 82 wherein the cation has the structure $N(R)_4$, wherein R is a C_1 - C_{12} hydrocarbyl and any two R groups may join together to form a cyclic structure with the nitrogen atom.
87. The composition of claim 86 wherein R is independently selected from the group consisting of C_1 - C_{12} alkyl, C_3 - C_{12} cycloalkyl and C_7 - C_{12} arylalkyl.
88. The composition of claim 82 wherein the cation has the structure $HN(R)_3$, wherein R is a C_1 - C_{12} hydrocarbyl and any two R groups may join together to form a cyclic structure with the nitrogen atom.
89. The composition of claim 88 wherein R is independently selected from the group consisting of C_1 - C_{12} alkyl, C_3 - C_{12} cycloalkyl and C_7 - C_{12} arylalkyl.
90. The composition of claim 82 wherein the cation has the structure $N(H)_2(R)_2$ wherein R is a C_1 - C_{12} hydrocarbyl and the two R groups may join together to form a cyclic structure with the nitrogen atom.
91. The composition of claim 90 wherein R is independently selected from the group consisting of C_1 - C_{12} alkyl, C_3 - C_{12} cycloalkyl and C_7 - C_{12} arylalkyl.
92. The composition of claim 82 wherein the cation is selected from the group consisting of ethylbutylammonium, 1-methylimidazole, 1-methylpiperidine, 1-methylpyrrolidine, 3-methoxypropylamine, triethylamine, bis(2-methoxyethyl)amine, diallylamine, dibutylamine, diisobutylamine, N,N-dimethylaminobutane, N,N-dimethylcyclohexylamine, N,N-dimethylheptylamine, N,N-dimethylhexylamine, triethanolamine, 1-ethylpiperidine, dicyclohexylamine, diisopropylamine, dipropylamine, N,N-dimethylisopropylamine, N-ethylbutylamine, tetraethylammonium, tripropylamine, 2-

methoxyethylamine, and N,N-dimethyloctylamine, and the anion is selected from the group consisting of acetate, trichloroacetate and trifluoroacetate.

93. The composition of any of claims 74 or 75 wherein the oligonucleotide comprises a chain of 6-100 nucleotides.

94. The composition of any of claims 74 or 75 wherein the oligonucleotide is DNA.

95. The composition of any of claims 74 or 75 further comprising an enzyme selected from polymerase and ligase.

96. The composition of any of claims 74 or 75 further comprising water.

97. The composition of claim 96 wherein the salt is completely dissolved in the water at a concentration of from 50 mM to 6 mM at room temperature.

98. The composition of claim 97 wherein the salt is completely dissolved in the water at a concentration of from 100 mM to 1 mM at room temperature.

99. A method of distinguishing between hybridization of a complementary nucleic acid target and a nucleic acid probe in which the probe and target are perfectly complementary and in which the probe and target have one or more base mismatches, comprising:

(a) mixing the nucleic acid target with the nucleic acid probe in a solution comprising a hybotrope;

(b) hybridizing at a discriminating temperature; and

(c) detecting probe hybridized to target,

thereby determining whether the nucleic acid probe and target are perfectly complementary or mismatched.

100. The method according to claim 99 wherein the nucleic acid probe is labeled with a radioactive molecule, fluorescent molecule, mass-spectrometry tag or enzyme.

101. The method according to claim 99 wherein the nucleic acid probe is from 6 to 40 bases.

102. The method according to claim 99 wherein the target nucleic acid probe is from 6 to 40 bases.

103. The method according to claim 99 wherein the hybotrope is selected from the group consisting of LiTCA, RbTCA, GuSCN, NaSCN, NaClO₄, KI, TMATCA TEATCA, TMATBA, TMTCA, TMTBA, TBATCA or TBATBA.

104. The method according to claim 99 wherein the hybotrope is a salt comprising an anion and a cation, wherein the anion is selected from acetate halogenated acetate, propionate and halogenated propionate, and the cation is selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

105. The method according to claim 99 wherein the hybotrope is present at a molarity of from about 0.5 M to about 6 M.

106. The method according to claim 99 wherein the probe nucleic acid is DNA.

107. The method according to claim 99 wherein the probe nucleic acid is RNA.

108. The method according to claim 99 wherein the target nucleic acid is DNA.

109. The method according to claim 99 wherein the target nucleic acid is RNA.

110. The method according to claim 99 wherein the target nucleic acid is affixed to a solid substrate.

111. The method according to claim 99, further comprising polymerase chain reaction.

112. A method of distinguishing between hybridization of a complementary nucleic acid target and a nucleic acid probe in which the probe and target are perfectly complementary and in which the probe and target have one or more base mismatches, comprising:

(a) mixing a nucleic acid target with a nucleic acid probe containing at least one abasic or deoxyNebularine substitution;

(b) hybridizing at a discriminating temperature; and

(c) detecting probe bound to the target,

thereby determining whether the nucleic acid probe and target are perfectly complementary or mismatched.

113. The method according to claim 112 wherein the nucleic acid probe is labeled with a radioactive molecule, fluorescent molecule, mass-spectrometry tag or enzyme.

114. The method according to claim 112 wherein the nucleic acid probe is from 6 to 40 bases.

115. The method according to claim 112 wherein the target nucleic acid probe is from 6 to 40 bases.

116. The method according to claim 112, further comprising a hybotrope.

117. The method according to claim 116 wherein the hybotrope is selected from the group consisting of LiTCA, RbTCA, GuSCN, NaSCN, NaClO₄, KI, TMATCA, TEATCA, TMATBA, TMTCA, TMTBA, TBATCA or TBATBA.

118. The method according to claim 116 wherein the hybotrope is a salt comprising an anion and a cation, wherein the anion is selected from acetate halogenated acetate, propionate and halogenated propionate, and the cation is selected from primary, secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

119. The method according to claim 116 wherein the hybotrope is present at a molarity of from about 0.5 M to about 6 M.

120. The method according to claim 112 wherein the probe nucleic acid is DNA.

121. The method according to claim 112 wherein the probe nucleic acid is RNA.

122. The method according to claim 112 wherein the target nucleic acid is DNA.

123. The method according to claim 112 wherein the target nucleic acid is RNA.

124. The method according to claim 112 wherein the target nucleic acid is affixed to a solid substrate.

125. A method of increasing discrimination in a nucleic acid synthesis procedure, comprising:

- (a) mixing a single-stranded nucleic acid target with an oligonucleotide primer in a solution comprising a hybotrope and a polymerase;
- (b) annealing the primer to the target at a discriminating temperature; and
- (c) synthesizing a complementary strand to the target to form a duplex.

126. The method according to claim 125 wherein the nucleic acid primer is labeled with a radioactive molecule, fluorescent molecule, mass-spectrometry tag or enzyme.

127. The method according to claim 125 wherein the nucleic acid primer is from 6 to 40 bases.

128. The method according to claim 125 wherein the hybotrope is selected from the group consisting of LiTCA, RbTCA, GuSCN, NaSCN, NaClO₄, KI, TMATCA TEATCA, TMATBA, TMTCA, TMTBA, TBATCA or TBATBA.

129. The method according to claim 125 wherein the hybotrope is a salt comprising an anion and a cation, wherein the anion is selected from acetate halogenated acetate, propionate and halogenated propionate, and the cation is selected from primary,

secondary and tertiary ammonium comprising 1-36 carbon atoms, and quaternary ammonium comprising 4-48 carbon atoms.

130. The method according to claim 125 wherein the hybotrope is present at a molarity of from about 0.5 M to about 6 M.

131. The method according to claim 125 wherein the steps of (a), (b), and (c) are repeated multiple times.

(54) Title: COMPOSITIONS AND METHODS FOR ENHANCING HYBRIDIZATION SPECIFICITY

(57) Abstract

Compositions and methods are provided for increasing the specificity of a probe nucleic acid for a target nucleic acid in a hybridization solution. An abasic residue, deoxyNebularine residue, or a hybotrope is used to increase specificity. A method is provided for identifying useful hybotropes, including salts, water miscible organic solvents, aprotic solvents and organic solvents, on the basis of enthalpy considerations. Hybotropic hybridization and modified oligonucleotides may be used in amplification reactions, such as PCR, sequence analysis methods, and genomic screening methods.

INTERNATIONAL SEARCH REPORT

Int'l Application No

PCT/US 97/17413

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 C12Q1/68

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 6 C12Q

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	WO 92 18649 A (MICROPROBE CORP) 29 October 1992	1,2, 12-14, 16-22, 28, 30-33, 39, 99-111, 125-131 112-124
Y	* see especially the claims * see the whole document --- -/-	

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

& document member of the same patent family
